IEEE 1588-2002 Timestamps

The IEEE 1588-2002 standard defines the Precision Time Protocol (PTP) that enables precise synchronization of clocks in a distributed network of devices. The PTP applies to systems communicating by local area networks supporting multicast messaging. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. It is frequently used in automation systems where a collection of communicating machines such as robots must be synchronized and hence operate over a common time base.^(†)

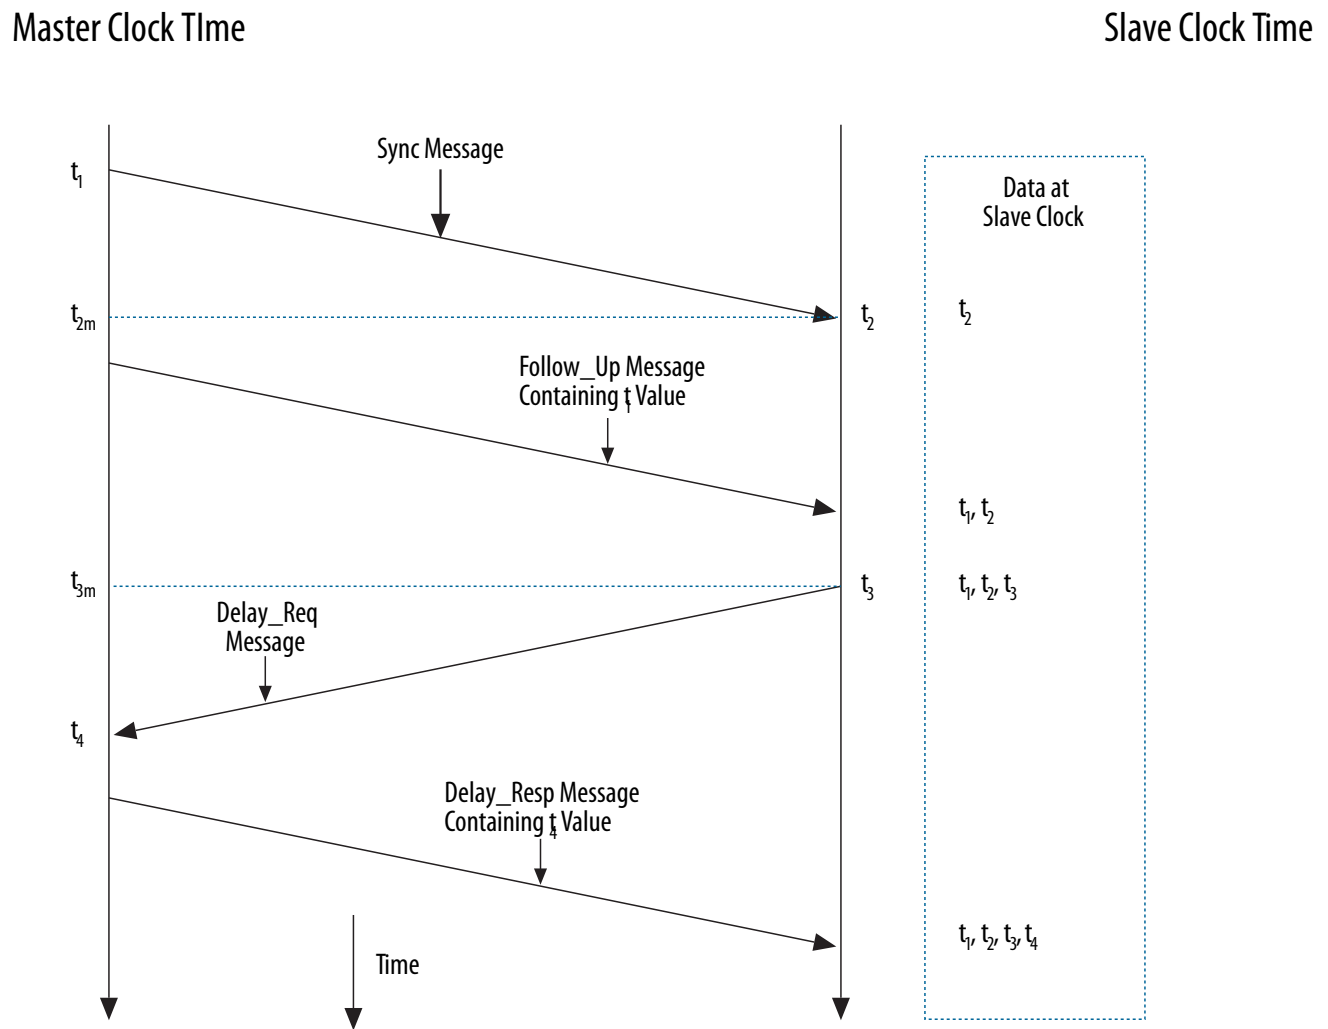

The PTP is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing and clock information.[†]

The following figure shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

^(†) Portions © 2015 Synopsys, Inc. Used with permission. All rights reserved. Synopsys & DesignWare are registered trademarks of Synopsys, Inc. Figure 17-13: Networked Time Synchronization

The PTP uses the following process for synchronizing a slave node to a master node by exchanging the PTP messages:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t_1 . This time must be captured, for Ethernet ports, at the PHY interface.[†]
2. The slave receives the sync message and also captures the exact time, t_2 , using its timing reference.[†]
3. The master sends a follow_up message to the slave, which contains t_1 information for later use.[†]
4. The slave sends a delay_req message to the master, noting the exact time, t_3 , at which this frame leaves the PHY interface.[†]
5. The master receives the message, capturing the exact time, t_4 , at which it enters its system.[†]
6. The master sends the t_4 information to the slave in the delay_resp message.[†]
7. The slave uses the four values of t_1 , t_2 , t_3 , and t_4 to synchronize its local timing reference to the master's timing reference.[†]

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at

the PHY interface. This timing information must be captured and returned to the software for the proper implementation of PTP with high accuracy.[†]

The EMAC is intended to support IEEE 1588 operation in all modes with a resolution of 20 ns. When the two EMACs are operating in an IEEE 1588 environment, the MPU subsystem is responsible for maintaining synchronization between the time counters internal to the two MACs.

The IEEE 1588 interface to the FPGA allows the FPGA to provide a source for the `emac_ptp_ref_clk` input as well to allow it to monitor the pulse per second output from each EMAC controller.

The EMAC component provides a hardware assisted implementation of the IEEE 1588 protocol. Hardware support is for timestamp maintenance. Timestamps are updated when receiving any frame on the PHY interface, and the receive descriptor is updated with this value. Timestamps are also updated when the SFD of a frame is transmitted and the transmit descriptor is updated accordingly.[†]

Related Information

<http://standards.ieee.org/findstds/index.html>

For details about the IEEE 1588-2002 standard, refer to IEEE Standard 1588-2002 - IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems, available on the IEEE Standards Association website.[†]

Reference Timing Source

To get a snapshot of the time, the EMAC takes the reference clock input and uses it to generate the reference time (64-bit) internally and capture timestamps.[†]

System Time Register Module

The 64-bit time is maintained in this module and updated using the input reference clock, `clk_ptp_ref`, which can be the `emac_ptp_clk` from the HPS or the `f2s_ptp_ref_clk` from the FPGA. The `emac_ptp_clk` in the HPS is a derivative of the `osc1_clk` and is configured in the clock manager. This input reference clock is the source for taking snapshots (timestamps) of Ethernet frames being transmitted or received at the PHY interface.

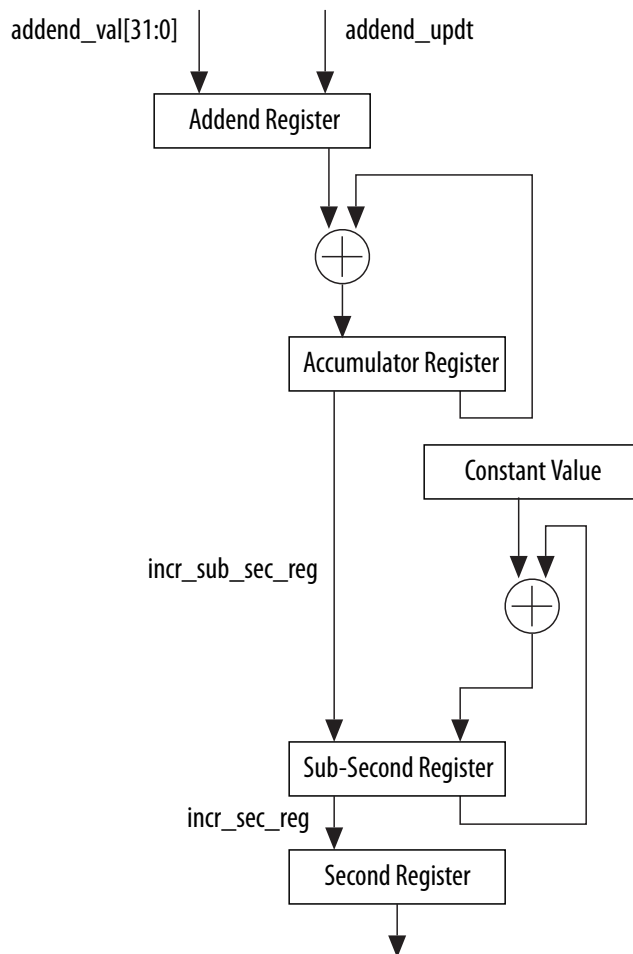

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, each EMAC's system time counter is written with the value in the Timestamp Update registers, while for system time correction, the offset value is added to or subtracted from the system time.

With the fine correction method, a slave clock's frequency drift with respect to the master clock is corrected over a period of time instead of in one clock, as in coarse correction. This protocol helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP sync message intervals.[†]

With this method, an accumulator sums up the contents of the Timestamp_Addend register, as shown in the figure below. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider.

Note: You must connect a PTP clock with a frequency higher than the frequency required for the specified accuracy.[†]

Figure 17-14: Algorithm for System Time Update Using Fine Method

The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division ratio (FreqDivisionRatio) is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock (`clk_ptp_ref_i`) is for example, 66 MHz, this ratio is calculated as $66 \text{ MHz} / 50 \text{ MHz} = 1.32$. Hence, the default addend value to program in the register is $232 / 1.32$, `0xC1F07C1F`.

If the reference clock drifts lower, to 65 MHz for example, the ratio is $65 / 50$, or 1.3 and the value to set in the addend register is $232 / 1.30$, or `0xC4EC4EC4`. If the clock drifts higher, to 67 MHz for example, the addend register must be set to `0xBF0B7672`. When the clock drift is nil, the default addend value of `0xC1F07C1F` ($232 / 1.32$) must be programmed.[†]

In the above figure, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20-ns steps).

The software must calculate the drift in frequency based on the Sync messages and update the Addend register accordingly.[†]

Initially, the slave clock is set with `FreqCompensationValue0` in the Addend register. This value is as follows:[†]

$$\text{FreqCompensationValue}_0 = 232 / \text{FreqDivisionRatio}^\dagger$$

If `MasterToSlaveDelay` is initially assumed to be the same for consecutive sync messages, the algorithm described below must be applied. After a few sync cycles, frequency lock occurs. The slave clock can then determine a precise `MasterToSlaveDelay` value and re-synchronize with the master using the new value.[†]

The algorithm is as follows:[†]

- At time `MasterSyncTimen` the master sends the slave clock a sync message. The slave receives this message when its local clock is `SlaveClockTimen` and computes `MasterClockTimen` as:[†]

$$\text{MasterClockTime}_n = \text{MasterSyncTime}_n + \text{MasterToSlaveDelay}_n^\dagger$$

- The master clock count for current sync cycle, `MasterClockCountn` is given by:[†]

$$\text{MasterClockCount}_n = \text{MasterClockTime}_n - \text{MasterClockTime}_{n-1}^\dagger$$

(assuming that `MasterToSlaveDelay` is the same for sync cycles n and $n - 1$)[†]

- The slave clock count for current sync cycle, `SlaveClockCountn` is given by:[†]

$$\text{SlaveClockCount}_n = \text{SlaveClockTime}_n - \text{SlaveClockTime}_{n-1}^\dagger$$

- The difference between master and slave clock counts for current sync cycle, `ClockDiffCountn` is given by:[†]

$$\text{ClockDiffCount}_n = \text{MasterClockCount}_n - \text{SlaveClockCount}_n^\dagger$$

- The frequency-scaling factor for the slave clock, `FreqScaleFactorn` is given by:[†]

$$\text{FreqScaleFactor}_n = (\text{MasterClockCount}_n + \text{ClockDiffCount}_n) / \text{SlaveClockCount}_n^\dagger$$

- The frequency compensation value for Addend register, `FreqCompensationValuen` is given by:[†]

$$\text{FreqCompensationValue}_n = \text{FreqScaleFactor}_n \times \text{FreqCompensationValue}_{n-1} - 1^\dagger$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, because of changing network propagation delays and operating conditions.[†]

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm corrects it at the cost of more Sync cycles.[†]

Transmit Path Functions

The MAC captures a timestamp when the start-of-frame data (SFD) is sent on the PHY interface. You can control the frames for which timestamps are captured on a per frame basis. In other words, each transmit frame can be marked to indicate whether a timestamp should be captured for that frame. †

You can use the control bits in the transmit descriptor to indicate whether a timestamp should be captured for a frame. The MAC returns the timestamp to the software inside the corresponding transmit descriptor, thus connecting the timestamp automatically to the specific PTP frame. The 64-bit timestamp information is written to the TDES2 and TDES3 fields. †

Receive Path Functions

The MAC captures the timestamp of all frames received on the PHY interface. The DMA returns the timestamp to the software in the corresponding receive descriptor. The timestamp is written only to the last receive descriptor. †

Timestamp Error Margin

According to the IEEE1588 specifications, a timestamp must be captured at the SFD of the transmitted and received frames at the PHY interface. Because the PHY interface receive and transmit clocks are not synchronous to the reference timestamp clock (`clk_ptp_ref`) a small amount of drift is introduced when a timestamp is moved between asynchronous clock domains. In the transmit path, the captured and reported timestamp has a maximum error margin of two PTP clocks, meaning that the captured timestamp has a reference timing source value that is occurred within two clocks after the SFD is transmitted on the PHY interface.

Similarly, in the receive path, the error margin is three PHY interface clocks, plus up to two PTP clocks. You can ignore the error margin due to the PHY interface clock by assuming that this constant delay is present in the system (or link) before the SFD data reaches the PHY interface of the MAC. †

Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, from the EMAC clock domain to the FPGA clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is four PHY interface clock cycles and three PTP clock cycles. If the delay between two timestamp captures is less than this amount, the MAC does not take a timestamp snapshot for the second frame.

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (20 ns resulting in 50 MHz) and the timing constraints achievable for logic operating on the PTP clock. In addition, the resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance. †

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes. Because the PHY interface clock frequency is fixed by the IEEE 1588 specification, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC. †

Table 17-18: Minimum PTP Clock Frequency Example

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency
100-Mbps full-duplex operation	168 MII clocks (128 clocks for a 64-byte frame + 24 clocks of min IFG + 16 clocks of preamble)	$(3 * \text{PTP}) + (4 * \text{MII}) \leq 168 * \text{MII}$, that is, $\sim 0.5 \text{ MHz } (168 - 4) * 40 \text{ ns} \div 3 = 2180 \text{ ns period}$
1000-Mbps half duplex operation	24 GMII clocks (4 for a jam pattern sent just after SFD because of collision + 12 IFG + 8 preamble)	$(3 * \text{PTP}) + 4 * \text{GMII} \leq 24 * \text{GMII}$, that is, 18.75 MHz

Related Information

<http://standards.ieee.org/findstds/index.html>

IEEE 1588-2008 Advanced Timestamps

In addition to the basic timestamp features mentioned in IEEE 1588-2002 Timestamps, the EMAC supports the following advanced timestamp features defined in the IEEE 1588-2008 standard.[†]

- Supports the IEEE 1588-2008 (version 2) timestamp format.[†]
- Provides an option to take a timestamp of all frames or only PTP-type frames.[†]
- Provides an option to take a timestamp of event messages only.[†]
- Provides an option to take the timestamp based on the clock type: ordinary, boundary, end-to-end, or peer-to-peer.[†]
- Provides an option to configure the EMAC to be a master or slave for ordinary and boundary clock.[†]
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status.[†]
- Provides an option to measure sub-second time in digital or binary format.[†]

Related Information

<http://standards.ieee.org/findstds/index.html>

For more information about advanced timestamp features, refer to the *IEEE Standard 1588 - 2008 IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control System*, available on the IEEE Standards Association website.

Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 version supports Peer-to-Peer PTP (Pdelay) messages in addition to SYNC, Delay Request, Follow-up, and Delay Response messages.[†]

Clock Types

The EMAC supports the following clock types defined in the IEEE 1588-2008 standard:

- Ordinary clock[†]
- Boundary clock[†]
- End-to-End transparent clock[†]
- Peer-to-Peer transparent clock[†]

Ordinary Clock

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device. [†]

The ordinary clock can be a grandmaster or a slave clock. It supports the following features:[†]

- Sends and receives PTP messages. The timestamp snapshot can be controlled as described in the `Timestamp_Control` register.[†]
- Maintains the data sets such as timestamp values.[†]

The table below shows the messages for which you can take the timestamp snapshot on the receive side for Master and slave nodes. For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the control bit (`tsver2ena`) and selecting the snapshot mode in the `Timestamp_Control` register.[†]

Table 17-19: Ordinary Clock: PTP Messages for Snapshot[†]

Master	Slave
Delay_Req	SYNC

Boundary Clock

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and are not forwarded. The PTP message type status given by the MAC helps you to identify the type of message and take appropriate action. The boundary clock is similar to the ordinary clock except for the following features:[†]

- The clock data sets are common to all ports of the boundary clock.[†]
- The local clock is common to all ports of the boundary clock. Therefore, the features of the ordinary clock are also applicable to the boundary clock.[†]

End-to-End Transparent Clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the ingress port to the egress port.[†]

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet inside the end-to-end transparent clock is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both ingress and egress ports only for PTP messages SYNC or Delay_req. You can take the snapshot by setting the snapshot select bits (`snaptypesel`) to b'10 in the `Timestamp_Control` register.[†]

The `snaptypsel` bits, along with bits 15 and 14 in the `Timestamp Control` register, decide the set of PTP packet types for which a snapshot needs to be taken. The encoding is shown in the table below:[†]

Table 17-20: Timestamp Snapshot Dependency on Register Bits[†]

X is defined as a "don't care" in the table.

<code>snaptypsel</code> (bits[17:16])	<code>tsmstrena</code> (bit 15)	<code>tseventena</code> (bit 14)	PTP Messages
b'00	X	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
b'00	0	1	SYNC
b'00	1	1	Delay_Req
b'01	X	0	SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up
b'01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
b'01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
b'10	X	X	SYNC, Delay_Req
b'11	X	X	Pdelay_Req, Pdelay_Resp

Peer-to-Peer Transparent Clock

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.[†]

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of `Pdelay_Req`, `Pdelay_Resp`, and `Pdelay_Resp_Follow_Up` messages with the link peer. The residence time of the `Pdelay_Req` and the associated `Pdelay_resp` packets is added and inserted into the correction field of the associated `Pdelay_Resp_Followup` packet.[†]

Therefore, support for taking snapshot for the event messages related to `Pdelay` is added as shown in the table below.[†]

Table 17-21: Peer-to-Peer Transparent Clock: PTP Messages for Snapshot[†]

PTP Messages
SYNC
<code>Pdelay_Req</code>
<code>Pdelay_Resp</code>

You can take the snapshot by setting the snapshot select bits (`snaptypsel`) to b'11 in the `Timestamp Control` register.[†]

Reference Timing Source

The EMAC supports the following reference timing source features defined in the IEEE 1588-2008 standard:

- 48-bit seconds field[†]
- Fixed pulse-per-second output[†]
- Flexible pulse-per-second output[†]
- Auxiliary snapshots (timestamps) with external events

Transmit Path Functions

The advanced timestamp feature is supported through the descriptors format.

Receive Path Functions

The MAC processes the received frames to identify valid PTP frames. You can control the snapshot of the time to be sent to the application, by using the following options:[†]

- Enable timestamp for all frames.[†]
- Enable timestamp for IEEE 1588 version 2 or version 1 timestamp.[†]
- Enable timestamp for PTP frames transmitted directly over Ethernet or UDP/IP Ethernet.[†]
- Enable timestamp snapshot for the received frame for IPv4 or IPv6.[†]
- Enable timestamp snapshot for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP) only.[†]
- Enable the node to be a master or slave and select the timestamp type to control the type of messages for which timestamps are taken.[†]

The DMA returns the timestamp to the software inside the corresponding transmit or receive descriptor.

Auxiliary Snapshot

The auxiliary snapshot feature allows you to store a snapshot (timestamp) of the system time based on an external event. The event is considered to be the rising edge of the sideband signal `ptp_aux_ts_trig_i` from the FPGA. One auxiliary snapshot input is available. The depth of the auxiliary snapshot FIFO buffer is 16.

The timestamps taken for any input are stored in a common FIFO buffer. The host can read Register 458 (Timestamp Status Register) to know which input's timestamp is available for reading at the top of this FIFO buffer.

Only 64-bits of the timestamp are stored in the FIFO. You can read the upper 16-bits of seconds from Register 457 (System Time - Higher Word Seconds Register) when it is present. When a snapshot is stored, the MAC indicates this to the host with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, then a snapshot trigger-missed status (`ATSSTM`) is set in Register 458 (Timestamp Status Register). This indicates that the latest auxiliary snapshot of the timestamp was not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full. When a host reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting Bit 19 (`ATSFC`) in Register 448 (Timestamp Control Register). When multiple snapshots are present in the FIFO, the count is indicated in Bits [27:25], `ATSNS`, of Register 458 (Timestamp Status Register).[†]

IEEE 802.3az Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) standardized by IEEE 802.3-az, version D2.0 is supported by the EMAC. It is supported by the MAC operating in 10/100/1000 Mbps rates. EEE is only supported when the EMAC

is configured to operate with the RGMII PHY interface operating in full-duplex mode. It cannot be used in half-duplex mode.

EEE enables the MAC to operate in Low-Power Idle (LPI) mode. Either end point of an Ethernet link can disable functionality to save power during periods of low link utilization. The MAC controls whether the system should enter or exit LPI mode and communicates this information to the PHY.[†]

Related Information

<http://www.ieee802.org/3/>

For details about the *IEEE 802.3az Energy Efficient Ethernet standard*, refer to the IEEE 802.3 Ethernet Working Group website.[†]

LPI Timers

Two timers internal to the EMAC are associated with LPI mode:

- LPI Link Status (LS) Timer[†]
- LPI Time Wait (TW) Timer[†]

The LPI LS timer counts, in ms, the time expired since the link status has come up. This timer is cleared every time the link goes down and is incremented when the link is up again and the terminal count as programmed by the software is reached. The PHY interface does not assert the LPI pattern unless the terminal count is reached. This protocol ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as one second in the IEEE standard 802.3-az, version D2.0. The LPI LS timer is 10 bits wide, so the software can program up to 1023 ms.[†]

The LPI TW timer counts, in μ s, the time expired since the deassertion of LPI. The terminal count of the timer is the value of resolved transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. The LPI TW timer is 16 bits wide, so the software can program up to 65535 μ s.[†]

The EMAC generates the LPI interrupt when the transmit or receive channel enters or exits the LPI state.[†]

Checksum Offload

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the EMAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path.

Supported offloading types:

- Transmit IP header checksum[†]
- Transmit TCP/UDP/ICMP checksum[†]
- Receive IP header checksum[†]
- Receive full checksum[†]

Frame Filtering

The EMAC implements the following types of filtering for receive frames.

Source Address or Destination Address Filtering

The Address Filtering Module checks the destination and source address field of each incoming packet.[†]

Unicast Destination Address Filter

Up to 128 MAC addresses for unicast perfect filtering are supported. The filter compares all 48 bits of the received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled, other addresses MacAddr1–MacAddr127 are selected with an individual enable bit. For MacAddr1–MacAddr31 addresses, you can mask each byte during comparison with the corresponding received DA byte. This enables group address filtering for the DA. The MacAddr32–MacAddr127 addresses do not have mask control and all six bytes of the MAC address are compared with the received six bytes of DA.[†]

In hash filtering mode, the filter performs imperfect filtering for unicast addresses using a 256-bit hash table. It uses the upper ten bits of the CRC of the received destination address to index the content of the hash table. A value of 0 selects Bit 0 of the selected register, and a value of 111111 binary selects Bit 63 of the Hash Table register. If the corresponding bit is set to one, the unicast frame is said to have passed the hash filter; otherwise, the frame has failed the hash filter.[†]

Multicast Destination Address Filter

The MAC can be programmed to pass all multicast frames. In Perfect Filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported. In hash filtering mode, the filter performs imperfect filtering using a 256-bit hash table. For hash filtering, it uses the upper ten bits of the CRC of the received multicast address to index the contents of the hash table. A value of 0 selects Bit 0 of the selected register and a value of 111111 binary selects Bit 63 of the Hash Table register. If the corresponding bit is set to one, then the multicast frame is said to have passed the hash filter; otherwise, the frame has failed the hash filter.[†]

Hash or Perfect Address Filter

The filter can be configured to pass a frame when its DA matches either the hash filter or the Perfect filter. This configuration applies to both unicast and multicast frames.[†]

Broadcast Address Filter

The filter does not filter any broadcast frames in the default mode. However, if the MAC is programmed to reject all broadcast frames, the filter drops any broadcast frame.[†]

Unicast Source Address Filter

The MAC can also perform a perfect filtering based on the source address field of the received frames. Group filtering with SA is also supported. You can filter a group of addresses by masking one or more bytes of the address.[†]

Inverse Filtering Operation (Invert the Filter Match Result at Final Output)

For both Destination and Source address filtering, there is an option to invert the filter-match result at the final output. The result of the unicast or multicast destination address filter is inverted in this mode.[†]

Destination and Source Address Filtering Summary

The tables below summarize the destination and source address filtering based on the type of frames received and the configuration of bits within the Mac_Frame_Filter register.[†]

Table 17-22: Destination Address Filtering[†]

Frame Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	Destination Address Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all frames
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multicast	1	X	X	X	X	X	X	Pass all frames
	X	X	X	X	X	1	X	Pass all frames
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause frames if PCF= 0X
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause frames if PCF = 0X
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause frames if PCF = 0X
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause frames if PCF=0X
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Paus frames if PCF = 0X
	0	1	X	1	1	0	X	Fail Hash on Perfect/Group filter match and drop Pause frames if PCF = 0X

Table 17-23: Source Address Filtering[†]

Frame Type	PR	DAIF	DBF	Source Address Filter Operation
Unicast	1	X	X	Pass all frames
	0	0	0	Pass status on Perfect or Group filter match but do not drop frames that fail.
	0	1	0	Fail on Perfect or Group filter match but do not drop frame
	0	0	1	Pass on Perfect or Group filter match and drop frames that fail
	0	1	1	Fail on Perfect or Group filter match and drop frames that fail

VLAN Filtering

The EMAC supports the two kinds of VLAN filtering:

- VLAN tag-based filtering[†]
- VLAN hash filtering[†]

VLAN Tag-Based Filtering

In the VLAN tag-based frame filtering, the MAC compares the VLAN tag of the received frame and provides the VLAN frame status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of the received VLAN tag to determine the perfect match. If VLAN tag filtering is enabled, the MAC forwards the VLAN-tagged frames along with VLAN tag match status and drops the VLAN frames that do not match. You can also enable the inverse matching for VLAN frames. In addition, you can enable matching of SVLAN tagged frames along with the default Customer Virtual Local Area Network (C-VLAN) tagged frames.[†]

VLAN Hash Filtering with a 16-Bit Hash Table

The MAC provides VLAN hash filtering with a 16-bit hash table. The MAC also supports the inverse matching of the VLAN frames. In inverse matching mode, when the VLAN tag of a frame matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a frame is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.[†]

Layer 3 and Layer 4 Filters

Layer 3 filtering refers to source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering. The frames are filtered in the following ways:[†]

- Matched frames[†]
- Unmatched frames[†]
- Non-TCP or UDP IP frames[†]

Matched Frames

The MAC forwards the frames, which match all enabled fields, to the application along with the status. The MAC gives the matched field status only if one of the following conditions is true:[†]

- All enabled Layer 3 and Layer 4 fields match.[†]
- At least one of the enabled field matches and other fields are bypassed or disabled.[†]

Using the CSR set, you can define up to four filters, identified as filter 0 through filter 3. When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides status of the lowest filter with filter 0 being the lowest and filter 3 being the highest. For example, if filter 0 and filter 1 match, the MAC gives the status corresponding to filter 0.[†]

Unmatched Frames

The MAC drops the frames that do not match any of the enabled fields. You can use the inverse match feature to block or drop a frame with specific TCP or UDP over IP fields and forward all other frames. You can configure the EMAC so that when a frame is dropped, it receives a partial frame with appropriate abort status or drops it completely.[†]

NonTCP or UDP IP Frames

By default, all non-TCP or UDP IP frames are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP frames.[†]

Clocks and Resets

Clock Structure

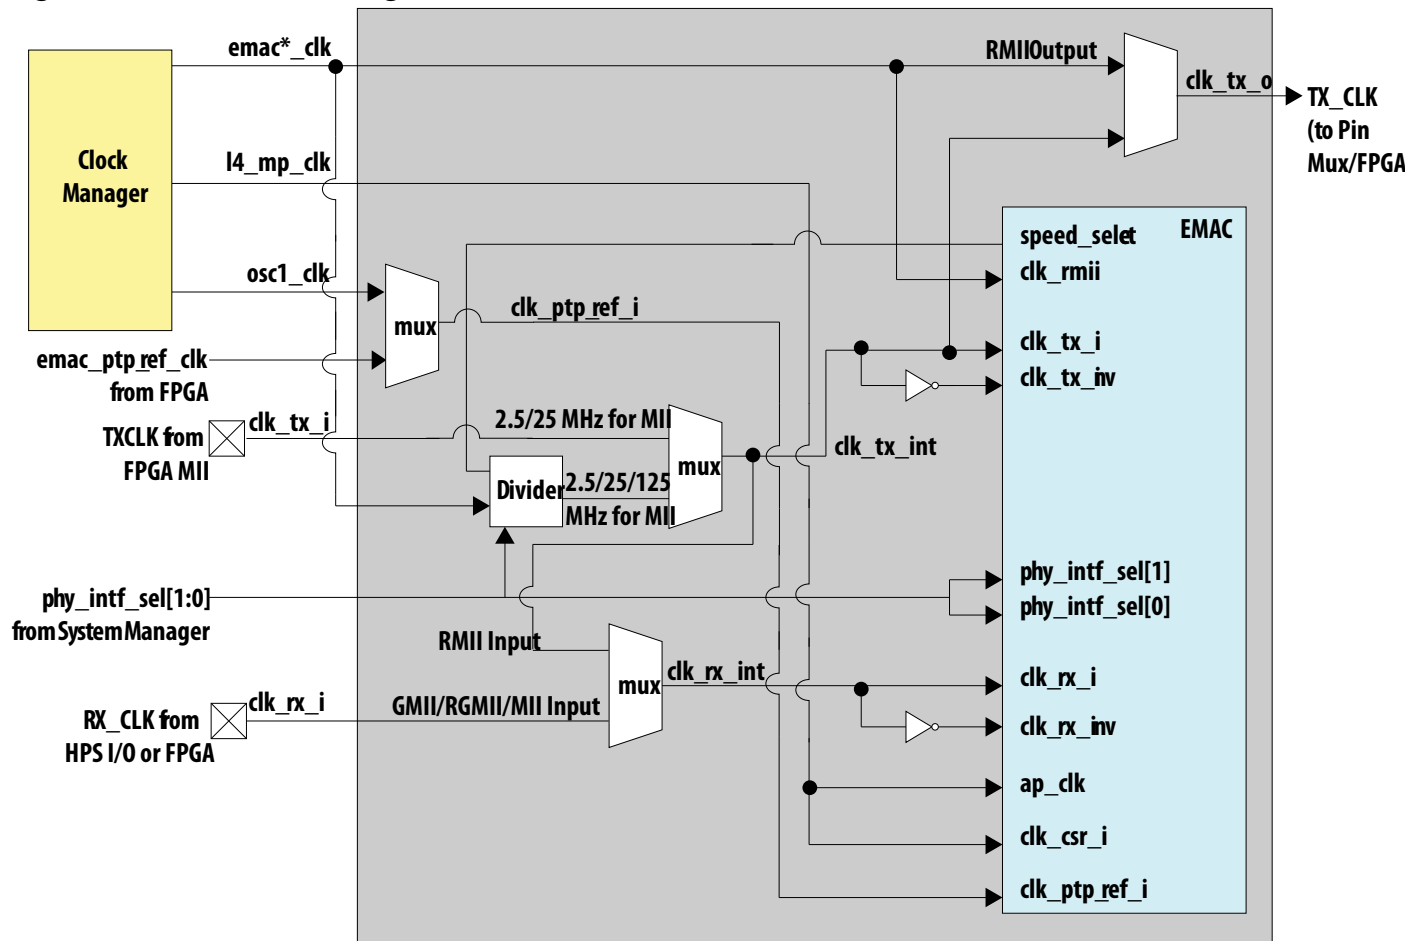

The Ethernet Controller received five input clocks and generates one output clock.

The EMAC controller provides the clock division and muxing necessary to generate the proper clocks for each of the PHY modes and data rates. The clock domains to the Ethernet controller are as follows

- l4_mp_clk clock
- EMAC RX clock
- EMAC TX clock
- clk_ptp_ref

The diagram below summarizes the clock domains of the EMAC module:

Figure 17-15: EMAC Clock Diagram

Clock Gating for EEE

For the RGMII PHY interface, you can gate the transmit clock for Energy Efficient Ethernet (EEE) applications.

Related Information

[Programming Guidelines for Energy Efficient Ethernet](#) on page 17-67

Reset

The EMAC module accepts a single reset input, `emac_rst_n`, which is active low.

Note: In all modes, the EMAC core depends on the PHY clocks to be active for the internal EMAC clock sources to be valid.

Taking the Ethernet MAC Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Interrupts

Interrupts are generated as a result of specific events in the EMAC and external PHY device. The interrupt status register indicates all conditions which may trigger an interrupt and the interrupt enable register determines which interrupts can propagate.

Ethernet MAC Programming Model

The initialization and configuration of the EMAC and its interface is a multi-step process that includes system register programming in the System Manager and Clock Manager and configuration of clocks in multiple domains.

Note: When the EMAC interfaces to HPS I/O and register content is being transferred to a different clock domain after a write operation, no further writes should occur to the same location until the first write is updated. Otherwise, the second write operation does not get updated to the destination clock domain. Thus, the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock, PHY transmit clock, or PTP clock).[†] If the CSR is accessed multiple times quickly, you must ensure that a minimum number of destination clock cycles have occurred between accesses.

Note: When using the EMAC with signals routed through the FPGA fabric, the minimum time required between two write accesses to the same register is 10 TX clock cycles.

System Level EMAC Configuration Registers

In addition to the registers in the Ethernet Controller, there are other system level registers in the Clock Manager, System Manager and Reset Manager that must be programmed in order to configure the EMAC and its interfaces.

The following table gives a summary of the important System Manager clock register bits that control operation of the EMAC. These register bits are static signals that must be set while the corresponding EMAC is in reset.

Table 17-24: System Manager Clock and Interface Settings

Register.Field	Description
ctrl.ptpclkssel_0	1588 PTP reference clock. This bit selects the source of the 1588 PTP reference clock.
ctrl.ptpclkssel_1	<ul style="list-style-type: none"> 0x0= osc1_clk (default from Clock Manager) 0x1= fpga_ptp_ref_clk (from FPGA fabric; in this case, the FPGA must be in usermode with an active reference clock)

Register.Field	Description
ctrl.physel_0	PHY Interface Select. These two bits set the PHY mode.
ctrl.physel_1	
	<ul style="list-style-type: none"> • 0x0= GMII or MII • 0x1= RGMII • 0x2= RMII (default) <p>Note: Selecting the 0x0 encoding routes the GMII/MII signals to the FPGA fabric only and selecting the 0x1 encoding routes the RGMII signals to the HPS only. 0x2 is not a valid encoding and depending on the interface selected, must be changed to 0x0 or 0x1 out of reset.</p>

The following table summarizes the important System Manager configuration register bits. All of the fields, except the AXI cache settings, are assumed to be static and must be set before the EMAC is brought out of reset. If the FPGA interface is used, the FPGA must be in user mode and enabled with the appropriate clock signals active before the EMAC can be brought out of reset.

Table 17-25: System Manager Static Control Settings

Register.Field	Description
module.emac_0	FPGA interface to EMAC disable. This field is used to disable signals from the FPGA to the EMAC modules that could potentially interfere with their normal operation
module.emac_1	
	<ul style="list-style-type: none"> • 0x0= Disable (default) • 0x1=Enable
l3master.awcache_1	EMAC AXI Master AxCACHE settings. It is recommended that these bits are set while the EMAC is idle or in reset.
l3master.awcache_0	
l3master.arcache_1	
l3master.arcache_0	

Various registers within the Clock Manager must also be configured in order for the EMAC controller to perform properly.

Table 17-26: Clock Manager Settings

Register.Field	Description
emac0clk.cnt	EMAC clock control. The cnt value in this register is used to divide the PLL VCO frequency to generate emac0clk and emac1clk.
emac1clk.cnt	

Register.Field	Description
en.emac0clk	emac0clk and emac1clk output enable.

EMAC FPGA Interface Initialization

To initialize the Ethernet controller to use the FPGA GMII/MII interface, specific software steps must be followed.

In general, the FPGA interface must be active in user mode with valid PHY clocks, the Ethernet Controller must be in a reset state during static configuration and the clock must be active and valid before the Ethernet Controller is brought out of reset.

1. After the HPS is released from cold or warm reset, reset the Ethernet Controller module by setting the appropriate `emac` bit in the `permodrst` register in the Reset Manager.
2. Configure the EMAC Controller clock to 250 MHz by programming the appropriate `cnt` value in the `emac*clk` register in the Clock Manager.
3. Bring the Ethernet PHY out of reset to verify that there are RX PHY clocks.
4. If the PTP clock source is from the FPGA, ensure that the FPGA `f2s_ptp_ref_clk` is active.
5. The soft GMII/MII adaptor must be loaded with active clocks propagating. The FPGA must be configured to user mode and a reset to the user soft FPGA IP may be required to propagate the PHY clocks to the HPS.
6. Once all clock sources are valid, apply the following clock settings:
 - a. Program the `physe1_*` field in the `ctrl` register of the System Manager (EMAC Group) to 0x0 to select the GMII/MII PHY interface.
 - b. If the PTP clock source is from the FPGA, set the `ptpclkse1_*` bit in the `ctrl` register (EMAC group) of the System Manager to be 0x1.
 - c. Enable the Ethernet Controller FPGA interface by setting the `emac_*` bit in the `module` register of the System Manager (FPGA Interface group).
7. Configure all of the EMAC static settings if the user requires a different setting from the default value. These settings include AXI AxCACHE signal values which are programmed in `l3` register in the EMAC group of the System Manager.
8. Execute a register read back to confirm the clock and static configuration settings are valid.
9. After confirming the settings are valid, software can clear the `emac` bit in the `permodrst` register of the Reset Manager to bring the EMAC out of reset.

When these steps are completed, general Ethernet controller and DMA software initialization and configuration can continue.

Note: These same steps can be applied to convert the HPS GMII to an RGMII, RMII or SGMII interface through the FPGA, except that in step 5 during FPGA configuration, you would load the appropriate soft adaptor for the interface and apply reset to it as well. The PHY interface select encoding would remain as 0x0. For the SGMII interface additional external transceiver logic would be required. Routing the Ethernet signals through the FPGA is useful for designs that are pin-limited in the HPS.

EMAC HPS Interface Initialization

To initialize the Ethernet controller to use the HPS interface, specific software steps must be followed including selecting the correct PHY interface through the System Manager.

In general, the Ethernet Controller must be in a reset state during static configuration and the clock must be active and valid before the Ethernet Controller is brought out of reset.

1. After the HPS is released from cold or warm reset, reset the Ethernet Controller module by setting the appropriate `emac` bit in the `permodrst` register in the Reset Manager.
2. Configure the EMAC Controller clock to 250 MHz by programming the appropriate `cnt` value in the `emac*clk` register in the Clock Manager.
3. Bring the Ethernet PHY out of reset to verify that there are RX PHY clocks.
4. When all the clocks are valid, program the following clock settings:
 - a. Set the `physe1_*` field in the `ctrl` register of the System Manager (EMAC Group) to 0x1 to select the RGMII PHY interface.
 - b. Disable the Ethernet Controller FPGA interfaces by clearing the `emac_*` bit in the `module` register of the System Manager (FPGA Interface group).
5. Configure all of the EMAC static settings if the user requires a different setting from the default value. These settings include AXI AxCache signal values, which are programmed in `l3` register in the EMAC group of the System Manager.
6. Execute a register read back to confirm the clock and static configuration settings are valid.
7. After confirming the settings are valid, software can clear the `emac` bit in the `permodrst` register of the Reset Manager to bring the EMAC out of reset..

When these steps are completed, general Ethernet controller and DMA software initialization and configuration can continue.

DMA Initialization

This section provides the instructions for initializing the DMA registers in the proper sequence. This initialization sequence can be done after the EMAC interface initialization has been completed. Perform the following steps to initialize the DMA:

1. Provide a software reset to reset all of the EMAC internal registers and logic. (DMA Register 0 (Bus Mode Register) – bit 0).[†]
2. Wait for the completion of the reset process (poll bit 0 of the DMA Register 0 (Bus Mode Register), which is only cleared after the reset operation is completed).[†]
3. Poll the bits of Register 11 (AHB or AXI Status) to confirm that all previously initiated (before software reset) or ongoing transactions are complete.

Note: If the application cannot poll the register after soft reset (because of performance reasons), then it is recommended that you continue with the next steps and check this register again (as mentioned in step 12 on page 1-65) before triggering the DMA operations.[†]

4. Program the following fields to initialize the Bus Mode Register by setting values in DMA Register 0 (Bus Mode Register):[†]
 - Mixed Burst and AAL
 - Fixed burst or undefined burst[†]
 - Burst length values and burst mode values[†]
 - Descriptor Length (only valid if Ring Mode is used)[†]
 - TX and RX DMA Arbitration scheme[†]
5. Program the interface options in Register 10 (AXI Bus Mode Register). If fixed burst-length is enabled, then select the maximum burst-length possible on the bus (bits[7:1]).[†]
6. Create a proper descriptor chain for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (bit 31 of descriptor should be set). When OSF mode is used, at least two descriptors are required.

7. Make sure that your software creates three or more different transmit or receive descriptors in the chain before reusing any of the descriptors.[†]
8. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (Register 3 (Receive Descriptor List Address Register) and Register 4 (Transmit Descriptor List Address Register) respectively).[†]
9. Program the following fields to initialize the mode of operation in Register 6 (Operation Mode Register):
 - Receive and Transmit Store And Forward[†]
 - Receive and Transmit Threshold Control (RTC and TTC)[†]
 - Hardware Flow Control enable[†]
 - Flow Control Activation and De-activation thresholds for MTL Receive and Transmit FIFO buffers (RFA and RFD)[†]
 - Error frame and undersized good frame forwarding enable[†]
 - OSF Mode[†]
10. Clear the interrupt requests, by writing to those bits of the status register (interrupt bits only) that are set. For example, by writing 1 into bit 16, the normal interrupt summary clears this bit (DMA Register 5 (Status Register)).[†]
11. Enable the interrupts by programming Register 7 (Interrupt Enable Register).[†]

Note: Perform step 12 on page 1-65 only if you did not perform step 3 on page 1-64.[†]
12. Read Register 11 (AHB or AXI Status) to confirm that all previous transactions are complete.[†]

Note: If any previous transaction is still in progress when you read the Register 11 (AHB or AXI Status), then it is strongly recommended to check the slave components addressed by the master interface.[†]
13. Start the receive and transmit DMA by setting SR (bit 1) and ST (bit 13) of the control register (DMA Register 6 (Operation Mode Register)).[†]

Detailed bit map of the descriptor structure

EMAC Initialization and Configuration

The following EMAC configuration operations can be performed after DMA initialization. If the EMAC initialization and configuration is done before the DMA is set up, then enable the MAC receiver (last step below) only after the DMA is active. Otherwise, received frames fill the RX FIFO buffer and overflow.

1. Program the EMAC Register 4 (GMII Address Register) for controlling the management cycles for the external PHY. Bits[15:11] of the GMII Address Register are written with the Physical Layer Address of the PHY before reading or writing. Bit 0 indicates if the PHY is busy and is set before reading or writing to the PHY management interface. †
2. Read the 16-bit data of Register 5 (GMII Data Register) from the PHY for link up, speed of operation, and mode of operation, by specifying the appropriate address value in bits 15-11 of Register 4 (GMII Address Register). †
3. Provide the MAC address registers (Register 16 (MAC Address0 High Register) and Register 17 (MAC Address0 Low Register)). Because 128 MAC addresses are supported, you must program the MAC addresses accordingly.
4. Program Register 2 (Hash Table High Register) and Register 3 (Hash Table Low Register).
5. Program the following fields to set the appropriate filters for the incoming frames in Register 1 (MAC Frame Filter): †

- Receive All †
 - Promiscuous mode †
 - Hash or Perfect Filter †
 - Unicast, multicast, broadcast, and control frames filter settings †
6. Program the following fields for proper flow control in Register 6 (Flow Control Register): †
 - Pause time and other pause frame control bits †
 - Receive and Transmit Flow control bits †
 - Flow Control Busy/Backpressure Activate †
 7. Program the Interrupt Mask register bits, as required and if applicable for your configuration. †
 8. Program the appropriate fields in Register 0 (MAC Configuration Register) to configure receive and transmit operation modes. After basic configuration is written, set bit 3 (TE) and bit 2 (RE) in this register to enable the receive and transmit state machines. †

Note: Do not change the configuration (such as duplex mode, speed, port, or loopback) when the EMAC DMA is actively transmitting or receiving. Software should change these parameters only when the EMAC DMA transmitter and receiver are not active.

Performing Normal Receive and Transmit Operation

For normal operation, perform the following steps: †

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive). †
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data. †
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and issuing a poll demand by writing 0 into the TX/RX poll demand registers, (Register 1 (Transmit Poll Demand Register) and Register 2 (Receive Poll Demand Register)). †
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (Register 18 (Current Host Transmit Descriptor Register) and Register 19 (Current Host Receive Descriptor Register)). †
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register 20 (Current Host Transmit Buffer Address Register) and Register 21 (Current Host Receive Buffer Address Register)). †

Stopping and Starting Transmission

Perform the following steps to pause the transmission for some time: †

1. Disable the transmit DMA (if applicable), by clearing bit 13 (Start or Stop Transmission Command) of Register 6 (Operation Mode Register). †
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Register 9 (Debug Register). †
3. Disable the EMAC transmitter and EMAC receiver by clearing Bit 3 (TE) and Bit 2 (RE) in Register 0 (MAC Configuration Register). †
4. Disable the receive DMA (if applicable), after making sure that the data in the RX FIFO buffer is transferred to the system memory (by reading Register 9 (Debug Register). †
5. Make sure that both the TX FIFO buffer and RX FIFO buffer are empty. †
6. To re-start the operation, first start the DMA and then enable the EMAC transmitter and receiver. †

Programming Guidelines for Energy Efficient Ethernet

Entering and Exiting the TX LPI Mode

The Energy Efficient Ethernet (EEE) feature is available in the EMAC. To use it, perform the following steps during EMAC initialization:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values. †
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop the RX clock in LPI mode.) †
3. Program Bits[16:5], LST, and Bits[15:0], TWT, in Register 13 (LPI Timers Control Register). †
4. Read the link status of the PHY chip by using the MDIO interface and update Bit 17 (PLS) of Register 12 (LPI Control and Status Register) accordingly. This update should be done whenever the link status in the PHY changes. †
5. Set Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to make the MAC enter the LPI state. The MAC enters the LPI mode after completing the transmission in progress and sets Bit 0 (TLPIEN). †

Note: To make the MAC enter the LPI state only after it completes the transmission of all queued frames in the TX FIFO buffer, you should set Bit 19 (LPITXA) in Register 12 (LPI Control and Status Register). †

Note: To switch off the transmit clock during the LPI state, use the `sbd_tx_clk_gating_ctrl_0` signal for gating the clock input. †

Note: To switch off the CSR clock or power to the rest of the system during the LPI state, you should wait for the TLPIEN interrupt of Register 12 (LPI Control and Status Register) to be generated. Restore the clocks before performing step 6 on page 1-67 when you want to come out of the LPI state. †

6. Clear Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to bring the MAC out of the LPI state. †

The MAC waits for the time programmed in Bits [15:0], TWT, before setting the TLPIEX interrupt status bit and resuming the transmission. †

Gating Off the CSR Clock in the LPI Mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode. †

Gating Off the CSR Clock in the RX LPI Mode

The following operations are performed when the MAC receives the LPI pattern from the PHY. †

1. The MAC RX enters the LPI mode and the RX LPI entry interrupt status [RLPIEN interrupt of Register 12 (LPI_Control_Status)] is set. †
2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the Register 12 (LPI_Control_Status). †

After the sbd_intr_o interrupt is asserted and the MAC TX is also in the LPI mode, you can gate off the CSR clock. If the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported or updated in the CSR. †

For restoring the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on lpi_intr_o (synchronous to clk_rx_i). The lpi_intr_o interrupt is cleared when Register 12 is read. †

Gating Off the CSR Clock in the TX LPI Mode

The following operations are performed when Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) is set: †

1. The Transmit LPI Entry interrupt (TLPIEN bit of Register 12) is set. †
2. The interrupt pin (sbd_intr_o) is asserted. The sbd_intr_o interrupt is cleared when the host reads the Register 12. †

After the sbd_intr_o interrupt is asserted and the MAC RX is also in the LPI mode, you can gate off the CSR clock. If the MAC RX is not in the LPI mode when you gate off the CSR clock, the events on the MAC receiver do not get reported or updated in the CSR. †

To restore the CSR clock, switch on the CSR clock when the MAC has to come out of the TX LPI mode. †

After the CSR clock is resumed, clear Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to bring the MAC out of the LPI mode. †

Programming Guidelines for Flexible Pulse-Per-Second (PPS) Output

Generating a Single Pulse on PPS

To generate single Pulse on PPS: †

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODESEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the start time of PPS signal output. †
2. Program the start time value in the Target Time registers (register 455 and 456). †
3. Program the width of the PPS signal output in Register 473 (PPS0 Width Register). †
4. Program Bits [3:0], PPSCMD, of Register 459 (PPS Control Register) to 0001 to instruct the MAC to generate a single pulse on the PPS signal output at the time programmed in the Target Time registers (register 455 and 456). †

Once the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance. To program the next pulse: †

1. Program the start time for the next pulse in the Target Time registers (register 455 and 456). This time should be more than the time at which the falling edge occurs for the previous pulse. †
2. Program the width of the next PPS signal output in Register 473 (PPS0 Width Register). †
3. Program Bits [3:0], PPSCMD, of Register 459 (PPS Control Register) to generate a single pulse on the PPS signal output after the time at which the previous pulse is de-asserted. And at the time programmed in Target Time registers. If you give this command before the previous pulse becomes

low, then the new command overwrites the previous command and the EMAC may generate only 1 extended pulse.

Generating a Pulse Train on PPS

To generate a pulse train on PPS: †

1. Program 11 or 10 (for an interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the start time of the PPS signal output. †
2. Program the start time value in the Target Time registers (register 455 and 456). †
3. Program the interval value between the train of pulses on the PPS signal output in Register 473 (PPS0 Width Register). †
4. Program the width of the PPS signal output in Register 473 (PPS0 Width Register). †
5. Program Bits[3:0], PPSCMD, of Register 459 (PPS Control Register) to 0010 to instruct the MAC to generate a train of pulses on the PPS signal output with the start time programmed in the Target Time registers (register 455 and 456). By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. †
6. Program the stop value in the Target Time registers (register 455 and 456). Ensure that Bit 31 (TSTRBUSY) of Register 456 (Target Time Nanoseconds Register) is clear before programming the Target Time registers (register 455 and 456) again. †
7. Program the PPSCMD field (bit 3:0) of Register 459 (PPS Control Register) to 0100 to stop the train of pulses on the PPS signal output after the programmed stop time specified in step 6 on page 1-69 elapses. †

You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in step 7 on page 1-69) by programming 0110 in the PPSCMD field before the time (programmed in step 6 on page 1-69) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in step 2 on page 1-69) elapses. †

Generating an Interrupt without Affecting the PPS

Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) enable you to program the Target Time registers (register 455 and 456) to do any one of the following: †

- Generate only interrupts. †
- Generate interrupts and the PPS start and stop time. †
- Generate only PPS start and stop time. †

To program the Target Time registers (register 455 and 456) to generate only interrupt events: †

1. Program 00 (for interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the target time interrupt. †
2. Program a target time value in the Target Time registers (register 455 and 456) to instruct the MAC to generate an interrupt when the target time elapses. If Bits [6:5], TRGTMODSEL, are changed (for

example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

Ethernet MAC Address Map and Register Definitions

The address map and register definitions pertain to the following modules:

- EMAC Module 0
- EMAC Module 1

GMAC Register Group Register Descriptions

GMAC Register Group

Offset: 0x0

[MAC_Configuration](#) on page 17-135

The MAC Configuration register establishes receive and transmit operating modes.

[MAC_Frame_Filter](#) on page 17-143

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

[GMII_Address](#) on page 17-149

The GMII Address register controls the management cycles to the external PHY through the management interface.

[GMII_Data](#) on page 17-151

The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

[Flow_Control](#) on page 17-152

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control block. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

[VLAN_Tag](#) on page 17-155

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. Because the VLAN Tag register is double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

[Version](#) on page 17-157

The Version registers identifies the version of the EMAC. This register contains two bytes: one specified by Synopsys to identify the core release number, and the other specified by Altera.

[Debug](#) on page 17-157

The Debug register gives the status of all main blocks of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC is in idle state (and FIFOs are empty) and no activity is going on in the data-paths.

LPI_Control_Status on page 17-161

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

LPI_Timers_Control on page 17-164

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Interrupt_Status on page 17-165

The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding optional feature is enabled.

Interrupt_Mask on page 17-168

The Interrupt Mask Register bits enable you to mask the interrupt signal because of the corresponding event in the Interrupt Status Register. The interrupt signal is `sbd_intr_o`.

MAC_Address0_High on page 17-169

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. Because the MAC address registers are double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

MAC_Address0_Low on page 17-170

The MAC Address0 Low register holds the lower 32 bits of the first 6-byte MAC address of the station.

MAC_Address1_High on page 17-171

The MAC Address1 High register holds the upper 16 bits of the 2nd 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address1_Low on page 17-174

The MAC Address1 Low register holds the lower 32 bits of the 2nd 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address2_High on page 17-175

The MAC Address2 High register holds the upper 16 bits of the 3rd 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address2 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address2_Low on page 17-178

The MAC Address2 Low register holds the lower 32 bits of the 3rd 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address3_High on page 17-179

The MAC Address3 High register holds the upper 16 bits of the 4th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address3 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address3_Low on page 17-182

The MAC Address3 Low register holds the lower 32 bits of the 4th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address4_High on page 17-183

The MAC Address4 High register holds the upper 16 bits of the 5th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address4 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address4_Low on page 17-186

The MAC Address4 Low register holds the lower 32 bits of the 5th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address5_High on page 17-187

The MAC Address5 High register holds the upper 16 bits of the 6th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address5 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address5_Low on page 17-190

The MAC Address5 Low register holds the lower 32 bits of the 6th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address6_High on page 17-191

The MAC Address6 High register holds the upper 16 bits of the 7th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address6 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address6_Low on page 17-194

The MAC Address6 Low register holds the lower 32 bits of the 7th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address7_High on page 17-195

The MAC Address7 High register holds the upper 16 bits of the 8th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address7 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address7_Low on page 17-198

The MAC Address7 Low register holds the lower 32 bits of the 8th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address8_High on page 17-199

The MAC Address8 High register holds the upper 16 bits of the 9th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address8 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address8_Low on page 17-202

The MAC Address8 Low register holds the lower 32 bits of the 9th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address9_High on page 17-203

The MAC Address9 High register holds the upper 16 bits of the 10th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address9 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address9_Low on page 17-206

The MAC Address9 Low register holds the lower 32 bits of the 10th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address10_High on page 17-207

The MAC Address10 High register holds the upper 16 bits of the 11th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address10 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address10_Low on page 17-210

The MAC Address10 Low register holds the lower 32 bits of the 11th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address11_High on page 17-211

The MAC Address11 High register holds the upper 16 bits of the 12th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address11 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address11_Low on page 17-214

The MAC Address11 Low register holds the lower 32 bits of the 12th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address12_High on page 17-215

The MAC Address12 High register holds the upper 16 bits of the 13th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address12 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address12_Low on page 17-218

The MAC Address12 Low register holds the lower 32 bits of the 13th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address13_High on page 17-219

The MAC Address13 High register holds the upper 16 bits of the 14th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address13 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address13_Low on page 17-222

The MAC Address13 Low register holds the lower 32 bits of the 14th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address14_High on page 17-223

The MAC Address14 High register holds the upper 16 bits of the 15th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address14 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address14_Low on page 17-226

The MAC Address14 Low register holds the lower 32 bits of the 15th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address15_High on page 17-227

The MAC Address15 High register holds the upper 16 bits of the 16th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address15 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address15_Low on page 17-230

The MAC Address15 Low register holds the lower 32 bits of the 16th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

SGMII_RGMII_SMII_Control_Status on page 17-231

The SGMII/RGMII/SMII Status register indicates the status signals received by the RGMII interface (selected at reset) from the PHY.

MMC_Control on page 17-232

The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

MMC_Receive_Interrupt on page 17-234

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

MMC_Transmit_Interrupt on page 17-240

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and the maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

MMC_Receive_Interrupt_Mask on page 17-245

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when the receive statistic counters reach half of their maximum value, or maximum value. This register is 32-bits wide.

MMC_Transmit_Interrupt_Mask on page 17-251

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or maximum value. This register is 32-bits wide.

txoctetcount_gb on page 17-257

Number of bytes transmitted, exclusive of preamble and retried bytes, in good and bad frames

txframecount_gb on page 17-258

Number of good and bad frames transmitted, exclusive of retried frames

txbroadcastframes_g on page 17-258

Number of good broadcast frames transmitted

txmulticastframes_g on page 17-259

Number of good multicast frames transmitted

tx64octets_gb on page 17-259

Number of good and bad frames transmitted with length 64 bytes, exclusive of preamble and retried frames

tx65to127octets_gb on page 17-260

Number of good and bad frames transmitted with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames

tx128to255octets_gb on page 17-261

Number of good and bad frames transmitted with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames

tx256to511octets_gb on page 17-261

Number of good and bad frames transmitted with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames

tx512to1023octets_gb on page 17-262

Number of good and bad frames transmitted with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames

tx1024tomaxoctets_gb on page 17-262

Number of good and bad frames transmitted with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames

txunicastframes_gb on page 17-263

Number of good and bad unicast frames transmitted

txmulticastframes_gb on page 17-264

Number of good and bad multicast frames transmitted

txbroadcastframes_gb on page 17-264

Number of good and bad broadcast frames transmitted

txunderflowerror on page 17-265

Number of frames aborted due to frame underflow error

txsinglecol_g on page 17-265

Number of successfully transmitted frames after a single collision in Half-duplex mode

txmulticol_g on page 17-266

Number of successfully transmitted frames after more than a single collision in Half-duplex mode

txdeferred on page 17-267

Number of successfully transmitted frames after a deferral in Halfduplex mode

txlatecol on page 17-267

Number of frames aborted due to late collision error

txexesscol on page 17-268

Number of frames aborted due to excessive (16) collision errors

txcarriererr on page 17-268

Number of frames aborted due to carrier sense error (no carrier or loss of carrier)

txoctetcnt on page 17-269

Number of bytes transmitted, exclusive of preamble, in good frames only

txframecount_g on page 17-269

Number of good frames transmitted

txexcessdef on page 17-270

Number of frames aborted due to excessive deferral error (deferred for more than two max-sized frame times)

txpauseframes on page 17-271

Number of good PAUSE frames transmitted

txvlanframes_g on page 17-271

Number of good VLAN frames transmitted, exclusive of retried frames

txoversize_g on page 17-272

Number of good and bad frames received

rxframecount_gb on page 17-272

Number of good and bad frames received

rxoctetcount_gb on page 17-273

Number of bytes received, exclusive of preamble, in good and bad frames

rxoctetcount_g on page 17-273

Number of bytes received, exclusive of preamble, only in good frames

rxbroadcastframes_g on page 17-274

Number of good broadcast frames received

rxmulticastframes_g on page 17-275

Number of good multicast frames received

rxrcrcerror on page 17-275

Number of frames received with CRC error

rxalignmenterror on page 17-276

Number of frames received with alignment (dribble) error. Valid only in 10/100 mode

rxrunterror on page 17-276

Number of frames received with runt (<64 bytes and CRC error) error

rxjabbererror on page 17-277

Number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames

rxundersize_g on page 17-278

Number of frames received with length less than 64 bytes, without any errors

rxoversize_g on page 17-278

Number of frames received with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames), without errors

rx64octets_gb on page 17-279

Number of good and bad frames received with length 64 bytes, exclusive of preamble

rx65to127octets_gb on page 17-279

Number of good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble

rx128to255octets_gb on page 17-280

Number of good and bad frames received with length between 128 and 255 (inclusive) bytes, exclusive of preamble

rx256to511octets_gb on page 17-281

Number of good and bad frames received with length between 256 and 511 (inclusive) bytes, exclusive of preamble

rx512to1023octets_gb on page 17-281

Number of good and bad frames received with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble

rx1024tomaxoctets_gb on page 17-282

Number of good and bad frames received with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames

rxunicastframes_g on page 17-282

Number of good unicast frames received

rxlengtherror on page 17-283

Number of frames received with length error (length type field not equal to frame size), for all frames with valid length field

rxoutofrangetype on page 17-284

Number of frames received with length field not equal to the valid frame size (greater than 1,500 but less than 1,536)

rxpauseframes on page 17-284

Number of good and valid PAUSE frames received

rxfifooverflow on page 17-285

Number of missed received frames due to FIFO overflow

rxvlanframes_gb on page 17-285

Number of good and bad VLAN frames received

rxwatchdogerror on page 17-286

Number of frames received with error due to watchdog timeout error (frames with a data load larger than 2,048 bytes)

rxrcverror on page 17-286

Number of frames received with Receive error or Frame Extension error on the GMII or MII interface.

[rxctrlframes_g](#) on page 17-287

Number of received good control frames.

[MMC_IPC_Receive_Interrupt_Mask](#) on page 17-288

This register maintains the mask for the interrupt generated from the receive IPC statistic counters.

[MMC_IPC_Receive_Interrupt](#) on page 17-294

This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

[rxipv4_gd_frms](#) on page 17-300

Number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload

[rxipv4_hdrerr_frms](#) on page 17-301

Number of IPv4 datagrams received with header (checksum, length, or version mismatch) errors

[rxipv4_nopay_frms](#) on page 17-301

Number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine

[rxipv4_frag_frms](#) on page 17-302

Number of good IPv4 datagrams with fragmentation

[rxipv4_udtbl_frms](#) on page 17-302

Number of good IPv4 datagrams received that had a UDP payload with checksum disabled

[rxipv6_gd_frms](#) on page 17-303

Number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads

[rxipv6_hdrerr_frms](#) on page 17-304

Number of IPv6 datagrams received with header errors (length or version mismatch)

[rxipv6_nopay_frms](#) on page 17-304

Number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers

[rxudp_gd_frms](#) on page 17-305

Number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented

[rxudp_err_frms](#) on page 17-305

Number of good IP datagrams whose UDP payload has a checksum error

[rxtcp_gd_frms](#) on page 17-306

Number of good IP datagrams with a good TCP payload

[rxtcp_err_frms](#) on page 17-306

Number of good IP datagrams whose TCP payload has a checksum error

[rxicmp_gd_frms](#) on page 17-307

Number of good IP datagrams with a good ICMP payload

[rxicmp_err_frms](#) on page 17-308

Number of good IP datagrams whose ICMP payload has a checksum error

[rxipv4_gd_octets](#) on page 17-308

Number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data

[rxipv4_hdrerr_octets](#) on page 17-309

Number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch).

The value in the Length field of IPv4 header is used to update this counter

[rxipv4_nopay_octets](#) on page 17-309

Number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter

[rxipv4_frag_octets](#) on page 17-310

Number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter

[rxipv4_udsbl_octets](#) on page 17-311

Number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes

[rxipv6_gd_octets](#) on page 17-311

Number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data

[rxipv6_hdrerr_octets](#) on page 17-312

Number of bytes received in IPv6 datagrams with header errors (length, version mismatch). The value in the IPv6 headers Length field is used to update this counter

[rxipv6_nopay_octets](#) on page 17-312

Number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 headers Length field is used to update this counter

[rxudp_gd_octets](#) on page 17-313

Number of bytes received in a good UDP segment. This counter does not count IP header bytes

[rxudp_err_octets](#) on page 17-313

Number of bytes received in a UDP segment that had checksum errors

[rxtcp_gd_octets](#) on page 17-314

Number of bytes received in a good TCP segment

[rxtcperroctets](#) on page 17-315

Number of bytes received in a TCP segment with checksum errors

[rxicmp_gd_octets](#) on page 17-315

Number of bytes received in a good ICMP segment

[rxicmp_err_octets](#) on page 17-316

Number of bytes received in an ICMP segment with checksum errors

[L3_L4_Control0](#) on page 17-316

This register controls the operations of the filter 0 of Layer 3 and Layer 4.

Layer4_Address0 on page 17-319

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg0 on page 17-320

For IPv4 frames, the Layer 3 Address 0 Register 0 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg0 on page 17-321

For IPv4 frames, the Layer 3 Address 1 Register 0 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg0 on page 17-322

For IPv4 frames, the Layer 3 Address 2 Register 0 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg0 on page 17-323

For IPv4 frames, the Layer 3 Address 3 Register 0 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

L3_L4_Control1 on page 17-324

This register controls the operations of the filter 0 of Layer 3 and Layer 4.

Layer4_Address1 on page 17-327

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg1 on page 17-328

For IPv4 frames, the Layer 3 Address 0 Register 1 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg1 on page 17-328

For IPv4 frames, the Layer 3 Address 1 Register 1 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg1 on page 17-329

For IPv4 frames, the Layer 3 Address 2 Register 1 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg1 on page 17-330

For IPv4 frames, the Layer 3 Address 3 Register 1 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

L3_L4_Control2 on page 17-331

This register controls the operations of the filter 2 of Layer 3 and Layer 4.

Layer4_Address2 on page 17-333

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg2 on page 17-334

For IPv4 frames, the Layer 3 Address 0 Register 2 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits [31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg2 on page 17-335

For IPv4 frames, the Layer 3 Address 1 Register 2 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits [63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg2 on page 17-336

For IPv4 frames, the Layer 3 Address 2 Register 2 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg2 on page 17-337

For IPv4 frames, the Layer 3 Address 3 Register 2 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

L3_L4_Control3 on page 17-338

This register controls the operations of the filter 0 of Layer 3 and Layer 4.

Layer4_Address3 on page 17-341

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg3 on page 17-342

For IPv4 frames, the Layer 3 Address 0 Register 3 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits [31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg3 on page 17-342

For IPv4 frames, the Layer 3 Address 1 Register 3 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits [63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg3 on page 17-343

For IPv4 frames, the Layer 3 Address 2 Register 3 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg3 on page 17-344

For IPv4 frames, the Layer 3 Address 3 Register 3 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

Hash_Table_Reg0 on page 17-345

This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper 8 bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Hash_Table_Reg1 on page 17-346

This register contains the second 32 bits of the hash table.

Hash_Table_Reg2 on page 17-346

This register contains the third 32 bits of the hash table.

Hash_Table_Reg3 on page 17-347

This register contains the fourth 32 bits of the hash table.

Hash_Table_Reg4 on page 17-347

This register contains the fifth 32 bits of the hash table.

Hash_Table_Reg5 on page 17-348

This register contains the sixth 32 bits of the hash table.

Hash_Table_Reg6 on page 17-349

This register contains the seventh 32 bits of the hash table.

Hash_Table_Reg7 on page 17-349

This register contains the eighth 32 bits of the hash table.

VLAN_Hash_Table_Reg on page 17-350

The 16-bit Hash table is used for group address filtering based on VLAN tag when Bit 18 (VTHM) of Register 7 (VLAN Tag Register) is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on Bit 16 (ETV) of VLAN Tag Register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper four bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. Notes: * Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Timestamp_Control on page 17-350

This register controls the operation of the System Time generator and the processing of PTP packets for timestamping in the Receiver.

Sub_Second_Increment on page 17-355

In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of `clk_ptp_ref_i`. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

System_Time_Seconds on page 17-356

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from `clk_ptp_ref_i` to `l3_sp_clk`).

System_Time_Nanoseconds on page 17-357

The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When TSCTRLSSR is set, each bit represents 1 ns and the maximum value is `0x3B9A_C9FF`, after which it rolls-over to zero.

System_Time_Seconds_Update on page 17-357

The System Time - Seconds Update register, along with the System Time - Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both of these registers before setting the TSINIT or TSUPDT bits in the Timestamp Control register.

System_Time_Nanoseconds_Update on page 17-358

Update system time

Timestamp_Addend on page 17-359

This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in Register 448). This register content is added to a 32-bit accumulator in every clock cycle (of `clk_ptp_ref_i`) and the system time is updated whenever the accumulator overflows.

Target_Time_Seconds on page 17-360

The Target Time Seconds register, along with Target Time Nanoseconds register, is used to schedule an interrupt event (Register 458[1] when Advanced Timestamping is enabled; otherwise, TS interrupt bit in Register14[9]) when the system time exceeds the value programmed in these registers.

Target_Time_Nanoseconds on page 17-360

Target time

System_Time_Higher_Word_Seconds on page 17-361

System time higher word

Timestamp_Status on page 17-362

Timestamp status. All bits except Bits[27:25] get cleared when the host reads this register.

PPS_Control on page 17-364

Controls timestamp Pulse-Per-Second output

Auxiliary_Timestamp_Nanoseconds on page 17-367

This register, along with Register 461 (Auxiliary Timestamp Seconds Register), gives the 64-bit timestamp stored as auxiliary snapshot. The two registers together form the read port of a 64-bit wide FIFO with a depth of 16. Multiple snapshots can be stored in this FIFO. The ATSNS bits in the Timestamp Status register indicate the fill-level of this FIFO. The top of the FIFO is removed only when the last byte of Register 461 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read. In big-endian mode, it corresponds to the reading of Bits[7:0] of Register 461 (Auxiliary Timestamp - Seconds Register).

Auxiliary_Timestamp_Seconds on page 17-368

Contains the higher 32 bits (Seconds field) of the auxiliary timestamp.

PPS0_Interval on page 17-369

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

PPS0_Width on page 17-369

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (ptp_pps_o[0]).

MAC_Address16_High on page 17-370

The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address16_Low on page 17-373

The MAC Address16 Low register holds the lower 32 bits of the 17th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address17_High on page 17-374

The MAC Address17 High register holds the upper 16 bits of the 18th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address17 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address17_Low on page 17-377

The MAC Address17 Low register holds the lower 32 bits of the 18th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address18_High on page 17-378

The MAC Address18 High register holds the upper 16 bits of the 19th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address18 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address18_Low on page 17-381

The MAC Address18 Low register holds the lower 32 bits of the 19th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address19_High on page 17-382

The MAC Address19 High register holds the upper 16 bits of the 20th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address19 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address19_Low on page 17-385

The MAC Address19 Low register holds the lower 32 bits of the 20th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address20_High on page 17-386

The MAC Address20 High register holds the upper 16 bits of the 21th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address20 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address20_Low on page 17-389

The MAC Address20 Low register holds the lower 32 bits of the 21th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address21_High on page 17-390

The MAC Address21 High register holds the upper 16 bits of the 22th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address21 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address21_Low on page 17-393

The MAC Address21 Low register holds the lower 32 bits of the 22th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address22_High on page 17-394

The MAC Address22 High register holds the upper 16 bits of the 23th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address22 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address22_Low on page 17-397

The MAC Address22 Low register holds the lower 32 bits of the 23th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address23_High on page 17-398

The MAC Address23 High register holds the upper 16 bits of the 24th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address23 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address23_Low on page 17-401

The MAC Address23 Low register holds the lower 32 bits of the 24th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address24_High on page 17-402

The MAC Address24 High register holds the upper 16 bits of the 25th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address24 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address24_Low on page 17-405

The MAC Address24 Low register holds the lower 32 bits of the 25th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address25_High on page 17-406

The MAC Address25 High register holds the upper 16 bits of the 26th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address25 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address25_Low on page 17-409

The MAC Address25 Low register holds the lower 32 bits of the 26th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address26_High on page 17-410

The MAC Address26 High register holds the upper 16 bits of the 27th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address26 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address26_Low on page 17-413

The MAC Address26 Low register holds the lower 32 bits of the 27th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address27_High on page 17-414

The MAC Address27 High register holds the upper 16 bits of the 28th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address27 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address27_Low on page 17-417

The MAC Address27 Low register holds the lower 32 bits of the 28th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address28_High on page 17-418

The MAC Address28 High register holds the upper 16 bits of the 29th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address28 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address28_Low on page 17-421

The MAC Address28 Low register holds the lower 32 bits of the 29th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address29_High on page 17-422

The MAC Address29 High register holds the upper 16 bits of the 30th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address29 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address29_Low on page 17-425

The MAC Address29 Low register holds the lower 32 bits of the 30th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address30_High on page 17-426

The MAC Address30 High register holds the upper 16 bits of the 31th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address30 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address30_Low on page 17-429

The MAC Address30 Low register holds the lower 32 bits of the 31th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address31_High on page 17-430

The MAC Address31 High register holds the upper 16 bits of the 32th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address31 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address31_Low on page 17-433

The MAC Address31 Low register holds the lower 32 bits of the 32th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address32_High on page 17-434

The MAC Address32 High register holds the upper 16 bits of the 33th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address32 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address32_Low on page 17-437

The MAC Address32 Low register holds the lower 32 bits of the 33th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address33_High on page 17-438

The MAC Address33 High register holds the upper 16 bits of the 34th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address33 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address33_Low on page 17-441

The MAC Address33 Low register holds the lower 32 bits of the 34th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address34_High on page 17-442

The MAC Address34 High register holds the upper 16 bits of the 35th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address34 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address34_Low on page 17-445

The MAC Address34 Low register holds the lower 32 bits of the 35th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address35_High on page 17-446

The MAC Address35 High register holds the upper 16 bits of the 36th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address35 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address35_Low on page 17-449

The MAC Address35 Low register holds the lower 32 bits of the 36th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address36_High on page 17-450

The MAC Address36 High register holds the upper 16 bits of the 37th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address36 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address36_Low on page 17-453

The MAC Address36 Low register holds the lower 32 bits of the 37th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address37_High on page 17-454

The MAC Address37 High register holds the upper 16 bits of the 38th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address37 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address37_Low on page 17-457

The MAC Address37 Low register holds the lower 32 bits of the 38th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address38_High on page 17-458

The MAC Address38 High register holds the upper 16 bits of the 39th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address38 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address38_Low on page 17-461

The MAC Address38 Low register holds the lower 32 bits of the 39th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address39_High on page 17-462

The MAC Address39 High register holds the upper 16 bits of the 40th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address39 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address39_Low on page 17-465

The MAC Address39 Low register holds the lower 32 bits of the 40th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address40_High on page 17-466

The MAC Address40 High register holds the upper 16 bits of the 41th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address40 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address40_Low on page 17-469

The MAC Address40 Low register holds the lower 32 bits of the 41th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address41_High on page 17-470

The MAC Address41 High register holds the upper 16 bits of the 42th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address41 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address41_Low on page 17-473

The MAC Address41 Low register holds the lower 32 bits of the 42th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address42_High on page 17-474

The MAC Address42 High register holds the upper 16 bits of the 43th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address42 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address42_Low on page 17-477

The MAC Address42 Low register holds the lower 32 bits of the 43th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address43_High on page 17-478

The MAC Address43 High register holds the upper 16 bits of the 44th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address43 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address43_Low on page 17-481

The MAC Address43 Low register holds the lower 32 bits of the 44th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address44_High on page 17-482

The MAC Address44 High register holds the upper 16 bits of the 45th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address44 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address44_Low on page 17-485

The MAC Address44 Low register holds the lower 32 bits of the 45th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address45_High on page 17-486

The MAC Address45 High register holds the upper 16 bits of the 46th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address45 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address45_Low on page 17-489

The MAC Address45 Low register holds the lower 32 bits of the 46th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address46_High on page 17-490

The MAC Address46 High register holds the upper 16 bits of the 47th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address46 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address46_Low on page 17-493

The MAC Address46 Low register holds the lower 32 bits of the 47th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address47_High on page 17-494

The MAC Address47 High register holds the upper 16 bits of the 48th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address47 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address47_Low on page 17-497

The MAC Address47 Low register holds the lower 32 bits of the 48th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address48_High on page 17-498

The MAC Address48 High register holds the upper 16 bits of the 49th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address48 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address48_Low on page 17-501

The MAC Address48 Low register holds the lower 32 bits of the 49th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address49_High on page 17-502

The MAC Address49 High register holds the upper 16 bits of the 50th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address49 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address49_Low on page 17-505

The MAC Address49 Low register holds the lower 32 bits of the 50th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address50_High on page 17-506

The MAC Address50 High register holds the upper 16 bits of the 51th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address50 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address50_Low on page 17-509

The MAC Address50 Low register holds the lower 32 bits of the 51th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address51_High on page 17-510

The MAC Address51 High register holds the upper 16 bits of the 52th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address51 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address51_Low on page 17-513

The MAC Address51 Low register holds the lower 32 bits of the 52th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address52_High on page 17-514

The MAC Address52 High register holds the upper 16 bits of the 53th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address52 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address52_Low on page 17-517

The MAC Address52 Low register holds the lower 32 bits of the 53th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address53_High on page 17-518

The MAC Address53 High register holds the upper 16 bits of the 54th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address53 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address53_Low on page 17-521

The MAC Address53 Low register holds the lower 32 bits of the 54th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address54_High on page 17-522

The MAC Address54 High register holds the upper 16 bits of the 55th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address54 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address54_Low on page 17-525

The MAC Address54 Low register holds the lower 32 bits of the 55th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address55_High on page 17-526

The MAC Address55 High register holds the upper 16 bits of the 56th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address55 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address55_Low on page 17-529

The MAC Address55 Low register holds the lower 32 bits of the 56th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address56_High on page 17-530

The MAC Address56 High register holds the upper 16 bits of the 57th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address56 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address56_Low on page 17-533

The MAC Address56 Low register holds the lower 32 bits of the 57th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address57_High on page 17-534

The MAC Address57 High register holds the upper 16 bits of the 58th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address57 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address57_Low on page 17-537

The MAC Address57 Low register holds the lower 32 bits of the 58th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address58_High on page 17-538

The MAC Address58 High register holds the upper 16 bits of the 59th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address58 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address58_Low on page 17-541

The MAC Address58 Low register holds the lower 32 bits of the 59th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address59_High on page 17-542

The MAC Address59 High register holds the upper 16 bits of the 60th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address59 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address59_Low on page 17-545

The MAC Address59 Low register holds the lower 32 bits of the 60th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address60_High on page 17-546

The MAC Address60 High register holds the upper 16 bits of the 61th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address60 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address60_Low on page 17-549

The MAC Address60 Low register holds the lower 32 bits of the 61th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address61_High on page 17-550

The MAC Address61 High register holds the upper 16 bits of the 62th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address61 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address61_Low on page 17-553

The MAC Address61 Low register holds the lower 32 bits of the 62th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address62_High on page 17-554

The MAC Address62 High register holds the upper 16 bits of the 63th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address62 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address62_Low on page 17-557

The MAC Address62 Low register holds the lower 32 bits of the 63th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address63_High on page 17-558

The MAC Address63 High register holds the upper 16 bits of the 64th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address63 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address63_Low on page 17-561

The MAC Address63 Low register holds the lower 32 bits of the 64th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address64_High on page 17-562

The MAC Address64 High register holds the upper 16 bits of the 65th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address64 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address64_Low on page 17-565

The MAC Address64 Low register holds the lower 32 bits of the 65th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address65_High on page 17-566

The MAC Address65 High register holds the upper 16 bits of the 66th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address65 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address65_Low on page 17-569

The MAC Address65 Low register holds the lower 32 bits of the 66th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address66_High on page 17-570

The MAC Address66 High register holds the upper 16 bits of the 67th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address66 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address66_Low on page 17-573

The MAC Address66 Low register holds the lower 32 bits of the 67th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address67_High on page 17-574

The MAC Address67 High register holds the upper 16 bits of the 68th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address67 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address67_Low on page 17-577

The MAC Address67 Low register holds the lower 32 bits of the 68th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address68_High on page 17-578

The MAC Address68 High register holds the upper 16 bits of the 69th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address68 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address68_Low on page 17-581

The MAC Address68 Low register holds the lower 32 bits of the 69th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address69_High on page 17-582

The MAC Address69 High register holds the upper 16 bits of the 70th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address69 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address69_Low on page 17-585

The MAC Address69 Low register holds the lower 32 bits of the 70th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address70_High on page 17-586

The MAC Address70 High register holds the upper 16 bits of the 71th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address70 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address70_Low on page 17-589

The MAC Address70 Low register holds the lower 32 bits of the 71th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address71_High on page 17-590

The MAC Address71 High register holds the upper 16 bits of the 72th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address71 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address71_Low on page 17-593

The MAC Address71 Low register holds the lower 32 bits of the 72th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address72_High on page 17-594

The MAC Address72 High register holds the upper 16 bits of the 73th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address72 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address72_Low on page 17-597

The MAC Address72 Low register holds the lower 32 bits of the 73th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address73_High on page 17-598

The MAC Address73 High register holds the upper 16 bits of the 74th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address73 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address73_Low on page 17-601

The MAC Address73 Low register holds the lower 32 bits of the 74th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address74_High on page 17-602

The MAC Address74 High register holds the upper 16 bits of the 75th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address74 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address74_Low on page 17-605

The MAC Address74 Low register holds the lower 32 bits of the 75th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address75_High on page 17-606

The MAC Address75 High register holds the upper 16 bits of the 76th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address75 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address75_Low on page 17-609

The MAC Address75 Low register holds the lower 32 bits of the 76th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address76_High on page 17-610

The MAC Address76 High register holds the upper 16 bits of the 77th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address76 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address76_Low on page 17-613

The MAC Address76 Low register holds the lower 32 bits of the 77th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address77_High on page 17-614

The MAC Address77 High register holds the upper 16 bits of the 78th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address77 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address77_Low on page 17-617

The MAC Address77 Low register holds the lower 32 bits of the 78th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address78_High on page 17-618

The MAC Address78 High register holds the upper 16 bits of the 79th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address78 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address78_Low on page 17-621

The MAC Address78 Low register holds the lower 32 bits of the 79th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address79_High on page 17-622

The MAC Address79 High register holds the upper 16 bits of the 80th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address79 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address79_Low on page 17-625

The MAC Address79 Low register holds the lower 32 bits of the 80th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address80_High on page 17-626

The MAC Address80 High register holds the upper 16 bits of the 81th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address80 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address80_Low on page 17-629

The MAC Address80 Low register holds the lower 32 bits of the 81th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address81_High on page 17-630

The MAC Address81 High register holds the upper 16 bits of the 82th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address81 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address81_Low on page 17-633

The MAC Address81 Low register holds the lower 32 bits of the 82th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address82_High on page 17-634

The MAC Address82 High register holds the upper 16 bits of the 83th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address82 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address82_Low on page 17-637

The MAC Address82 Low register holds the lower 32 bits of the 83th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address83_High on page 17-638

The MAC Address83 High register holds the upper 16 bits of the 84th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address83 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address83_Low on page 17-641

The MAC Address83 Low register holds the lower 32 bits of the 84th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address84_High on page 17-642

The MAC Address84 High register holds the upper 16 bits of the 85th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address84 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address84_Low on page 17-645

The MAC Address84 Low register holds the lower 32 bits of the 85th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address85_High on page 17-646

The MAC Address85 High register holds the upper 16 bits of the 86th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address85 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address85_Low on page 17-649

The MAC Address85 Low register holds the lower 32 bits of the 86th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address86_High on page 17-650

The MAC Address86 High register holds the upper 16 bits of the 87th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address86 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address86_Low on page 17-653

The MAC Address86 Low register holds the lower 32 bits of the 87th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address87_High on page 17-654

The MAC Address87 High register holds the upper 16 bits of the 88th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address87 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address87_Low on page 17-657

The MAC Address87 Low register holds the lower 32 bits of the 88th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address88_High on page 17-658

The MAC Address88 High register holds the upper 16 bits of the 89th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address88 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address88_Low on page 17-661

The MAC Address88 Low register holds the lower 32 bits of the 89th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address89_High on page 17-662

The MAC Address89 High register holds the upper 16 bits of the 90th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address89 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address89_Low on page 17-665

The MAC Address89 Low register holds the lower 32 bits of the 90th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address90_High on page 17-666

The MAC Address90 High register holds the upper 16 bits of the 91th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address90 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address90_Low on page 17-669

The MAC Address90 Low register holds the lower 32 bits of the 91th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address91_High on page 17-670

The MAC Address91 High register holds the upper 16 bits of the 92th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address91 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address91_Low on page 17-673

The MAC Address91 Low register holds the lower 32 bits of the 92th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address92_High on page 17-674

The MAC Address92 High register holds the upper 16 bits of the 93th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address92 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address92_Low on page 17-677

The MAC Address92 Low register holds the lower 32 bits of the 93th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address93_High on page 17-678

The MAC Address93 High register holds the upper 16 bits of the 94th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address93 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address93_Low on page 17-681

The MAC Address93 Low register holds the lower 32 bits of the 94th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address94_High on page 17-682

The MAC Address94 High register holds the upper 16 bits of the 95th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address94 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address94_Low on page 17-685

The MAC Address94 Low register holds the lower 32 bits of the 95th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address95_High on page 17-686

The MAC Address95 High register holds the upper 16 bits of the 96th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address95 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address95_Low on page 17-689

The MAC Address95 Low register holds the lower 32 bits of the 96th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address96_High on page 17-690

The MAC Address96 High register holds the upper 16 bits of the 97th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address96 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address96_Low on page 17-693

The MAC Address96 Low register holds the lower 32 bits of the 97th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address97_High on page 17-694

The MAC Address97 High register holds the upper 16 bits of the 98th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address97 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address97_Low on page 17-697

The MAC Address97 Low register holds the lower 32 bits of the 98th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address98_High on page 17-698

The MAC Address98 High register holds the upper 16 bits of the 99th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address98 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address98_Low on page 17-701

The MAC Address98 Low register holds the lower 32 bits of the 99th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address99_High on page 17-702

The MAC Address99 High register holds the upper 16 bits of the 100th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address99 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address99_Low on page 17-705

The MAC Address99 Low register holds the lower 32 bits of the 100th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address100_High on page 17-706

The MAC Address100 High register holds the upper 16 bits of the 101th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address100 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address100_Low on page 17-709

The MAC Address100 Low register holds the lower 32 bits of the 101th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address101_High on page 17-710

The MAC Address101 High register holds the upper 16 bits of the 102th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address101 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address101_Low on page 17-713

The MAC Address101 Low register holds the lower 32 bits of the 102th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address102_High on page 17-714

The MAC Address102 High register holds the upper 16 bits of the 103th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address102 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address102_Low on page 17-717

The MAC Address102 Low register holds the lower 32 bits of the 103th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address103_High on page 17-718

The MAC Address103 High register holds the upper 16 bits of the 104th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address103 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address103_Low on page 17-721

The MAC Address103 Low register holds the lower 32 bits of the 104th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address104_High on page 17-722

The MAC Address104 High register holds the upper 16 bits of the 105th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address104 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address104_Low on page 17-725

The MAC Address104 Low register holds the lower 32 bits of the 105th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address105_High on page 17-726

The MAC Address105 High register holds the upper 16 bits of the 106th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address105 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address105_Low on page 17-729

The MAC Address105 Low register holds the lower 32 bits of the 106th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address106_High on page 17-730

The MAC Address106 High register holds the upper 16 bits of the 107th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address106 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address106_Low on page 17-733

The MAC Address106 Low register holds the lower 32 bits of the 107th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address107_High on page 17-734

The MAC Address107 High register holds the upper 16 bits of the 108th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address107 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address107_Low on page 17-737

The MAC Address107 Low register holds the lower 32 bits of the 108th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address108_High on page 17-738

The MAC Address108 High register holds the upper 16 bits of the 109th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address108 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address108_Low on page 17-741

The MAC Address108 Low register holds the lower 32 bits of the 109th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address109_High on page 17-742

The MAC Address109 High register holds the upper 16 bits of the 110th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address109 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address109_Low on page 17-745

The MAC Address109 Low register holds the lower 32 bits of the 110th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address110_High on page 17-746

The MAC Address110 High register holds the upper 16 bits of the 111th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address110 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address110_Low on page 17-749

The MAC Address110 Low register holds the lower 32 bits of the 111th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address111_High on page 17-750

The MAC Address111 High register holds the upper 16 bits of the 112th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address111 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address111_Low on page 17-753

The MAC Address111 Low register holds the lower 32 bits of the 112th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address112_High on page 17-754

The MAC Address112 High register holds the upper 16 bits of the 113th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address112 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address112_Low on page 17-757

The MAC Address112 Low register holds the lower 32 bits of the 113th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address113_High on page 17-758

The MAC Address113 High register holds the upper 16 bits of the 114th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address113 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address113_Low on page 17-761

The MAC Address113 Low register holds the lower 32 bits of the 114th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address114_High on page 17-762

The MAC Address114 High register holds the upper 16 bits of the 115th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address114 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address114_Low on page 17-765

The MAC Address114 Low register holds the lower 32 bits of the 115th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address115_High on page 17-766

The MAC Address115 High register holds the upper 16 bits of the 116th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address115 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address115_Low on page 17-769

The MAC Address115 Low register holds the lower 32 bits of the 116th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address116_High on page 17-770

The MAC Address116 High register holds the upper 16 bits of the 117th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address116 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address116_Low on page 17-773

The MAC Address116 Low register holds the lower 32 bits of the 117th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address117_High on page 17-774

The MAC Address117 High register holds the upper 16 bits of the 118th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address117 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address117_Low on page 17-777

The MAC Address117 Low register holds the lower 32 bits of the 118th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address118_High on page 17-778

The MAC Address118 High register holds the upper 16 bits of the 119th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address118 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address118_Low on page 17-781

The MAC Address118 Low register holds the lower 32 bits of the 119th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address119_High on page 17-782

The MAC Address119 High register holds the upper 16 bits of the 120th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address119 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address119_Low on page 17-785

The MAC Address119 Low register holds the lower 32 bits of the 120th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address120_High on page 17-786

The MAC Address120 High register holds the upper 16 bits of the 121th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address120 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address120_Low on page 17-789

The MAC Address120 Low register holds the lower 32 bits of the 121th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address121_High on page 17-790

The MAC Address121 High register holds the upper 16 bits of the 122th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address121 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address121_Low on page 17-793

The MAC Address121 Low register holds the lower 32 bits of the 122th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address122_High on page 17-794

The MAC Address122 High register holds the upper 16 bits of the 123th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address122 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address122_Low on page 17-797

The MAC Address122 Low register holds the lower 32 bits of the 123th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address123_High on page 17-798

The MAC Address123 High register holds the upper 16 bits of the 124th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address123 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address123_Low on page 17-801

The MAC Address123 Low register holds the lower 32 bits of the 124th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address124_High on page 17-802

The MAC Address124 High register holds the upper 16 bits of the 125th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address124 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address124_Low on page 17-805

The MAC Address124 Low register holds the lower 32 bits of the 125th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address125_High on page 17-806

The MAC Address125 High register holds the upper 16 bits of the 126th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address125 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address125_Low on page 17-809

The MAC Address125 Low register holds the lower 32 bits of the 126th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address126_High on page 17-810

The MAC Address126 High register holds the upper 16 bits of the 127th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address126 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address126_Low on page 17-813

The MAC Address126 Low register holds the lower 32 bits of the 127th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address127_High on page 17-814

The MAC Address127 High register holds the upper 16 bits of the 128th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address127 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address127_Low on page 17-817

The MAC Address127 Low register holds the lower 32 bits of the 128th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Configuration

The MAC Configuration register establishes receive and transmit operating modes.

Module Instance	Base Address	Register Address

MAC_Configuration Fields

Bit	Name	Description	Access	Reset						
27	twokpe	When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets. When Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 2K bytes as Giant frames. When this bit is reset and Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 1,518 bytes (1,522 bytes for tagged) as Giant frames. When Bit 20 (Jumbo Enable) is set, setting this bit has no effect on Giant Frame status.	RW	0x0						
25	cst	When set, the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0x0600) are stripped and dropped before forwarding the frame to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Strip Ether Frames Off</td> </tr> <tr> <td>0x1</td> <td>Strip Ether Frames On</td> </tr> </tbody> </table>	Value	Description	0x0	Strip Ether Frames Off	0x1	Strip Ether Frames On	RW	0x0
Value	Description									
0x0	Strip Ether Frames Off									
0x1	Strip Ether Frames On									
24	tc	When set, this bit enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII. When this bit is reset, no such information is driven to the PHY. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Enables Transmission of duplex</td> </tr> <tr> <td>0x0</td> <td>Disables Transmission to Phy</td> </tr> </tbody> </table>	Value	Description	0x1	Enables Transmission of duplex	0x0	Disables Transmission to Phy	RW	0x0
Value	Description									
0x1	Enables Transmission of duplex									
0x0	Disables Transmission to Phy									
23	wd	When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive frames of up to 16,384 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the frame being received. The MAC cuts off any bytes received after 2,048 bytes. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Enable MAC cutoff > 2048Bytes</td> </tr> <tr> <td>0x1</td> <td>Disable Watchdog</td> </tr> </tbody> </table>	Value	Description	0x0	Enable MAC cutoff > 2048Bytes	0x1	Disable Watchdog	RW	0x0
Value	Description									
0x0	Enable MAC cutoff > 2048Bytes									
0x1	Disable Watchdog									

Bit	Name	Description	Access	Reset						
22	jd	<p>When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer frames of up to 16,384 bytes. When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2,048 bytes of data (10,240 if JE is set high) during transmission.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>MAC cuts off TX > 2048</td> </tr> <tr> <td>0x1</td> <td>Jabber Timer Disabled</td> </tr> </tbody> </table>	Value	Description	0x0	MAC cuts off TX > 2048	0x1	Jabber Timer Disabled	RW	0x0
Value	Description									
0x0	MAC cuts off TX > 2048									
0x1	Jabber Timer Disabled									
21	be	<p>When this bit is set, the MAC allows frame bursting during transmission in the GMII half-duplex mode.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Frame Burst Enable OFF</td> </tr> <tr> <td>0x1</td> <td>Frame Burst Enable ON</td> </tr> </tbody> </table>	Value	Description	0x0	Frame Burst Enable OFF	0x1	Frame Burst Enable ON	RW	0x0
Value	Description									
0x0	Frame Burst Enable OFF									
0x1	Frame Burst Enable ON									
20	je	<p>When this bit is set, the MAC allows Jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames) without reporting a giant frame error in the receive frame status.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Report Jumbo Frame Error</td> </tr> <tr> <td>0x1</td> <td>Ignore Jumbo Frame Error</td> </tr> </tbody> </table>	Value	Description	0x0	Report Jumbo Frame Error	0x1	Ignore Jumbo Frame Error	RW	0x0
Value	Description									
0x0	Report Jumbo Frame Error									
0x1	Ignore Jumbo Frame Error									

Bit	Name	Description	Access	Reset																		
19:17	ifg	<p>These bits control the minimum IFG between frames during transmission. In the half-duplex mode, the minimum IFG can be configured only for 64 bit times (IFG = 100). Lower values are not considered. In the 1000-Mbps mode, the minimum IFG supported is 80 bit times (and above).</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Inter Frame Gap 96 bit times</td> </tr> <tr> <td>0x1</td> <td>Inter Frame Gap 88 bit times</td> </tr> <tr> <td>0x2</td> <td>Inter Frame Gap 80 bit times</td> </tr> <tr> <td>0x3</td> <td>Inter Frame Gap 72 bit times</td> </tr> <tr> <td>0x4</td> <td>Inter Frame Gap 64 bit times</td> </tr> <tr> <td>0x5</td> <td>Inter Frame Gap 56 bit times</td> </tr> <tr> <td>0x6</td> <td>Inter Frame Gap 48 bit times</td> </tr> <tr> <td>0x7</td> <td>Inter Frame Gap 40 bit times</td> </tr> </tbody> </table>	Value	Description	0x0	Inter Frame Gap 96 bit times	0x1	Inter Frame Gap 88 bit times	0x2	Inter Frame Gap 80 bit times	0x3	Inter Frame Gap 72 bit times	0x4	Inter Frame Gap 64 bit times	0x5	Inter Frame Gap 56 bit times	0x6	Inter Frame Gap 48 bit times	0x7	Inter Frame Gap 40 bit times	RW	0x0

10	ipc	<p>When this bit is set, the MAC calculates the 16-bit ones complement of the ones complement sum of all received Ethernet frame payloads. It also checks whether the IPv4 Header checksum (assumed to be bytes 2526 or 2930 (VLAN-tagged) of the received Ethernet frame) is correct for the received frame and gives the status in the receive status word. The MAC also appends the 16-bit checksum calculated for the IP header datagram payload (bytes after the IPv4 header) and appends it to the Ethernet frame transferred to the application (when Type 2 COE is deselected). When this bit is reset, this function is disabled. When Type 2 COE is selected, this bit, when set, enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled and the corresponding PCE and IP HCE status bits are always cleared.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Checksum Enabled</td> </tr> <tr> <td>0x0</td> <td>Checksum Disabled</td> </tr> </tbody> </table>	Value	Description	0x1	Checksum Enabled	0x0	Checksum Disabled	RW	0x0

Bit	Name	Description	Access	Reset						
4	dc	<p>When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status, when the transmit state machine is deferred for more than 24,288 bit times in the 10 or 100 Mbps mode. If the MAC is configured for 1000 Mbps operation, or if the Jumbo frame mode is enabled in the 10 or 100 Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on GMII or MII. Defer time is not cumulative. When the transmitter defers for 10,000 bit times, it transmits, collides, backs off, and then defers again after completion of back-off. The deferral timer resets to 0 and restarts. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Deferral Check Enabled</td> </tr> <tr> <td>0x0</td> <td>Deferral Check Disabled</td> </tr> </tbody> </table>	Value	Description	0x1	Deferral Check Enabled	0x0	Deferral Check Disabled	RW	0x0

MAC_Frame_Filter

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

5:2	cr	<p>The CSR Clock Range selection determines the frequency of the MDC clock according to the l3_sp_clk frequency used in your design. The suggested range of l3_sp_clk frequency applicable for each value (when Bit[5] = 0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz. When Bit 5 is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when l3_sp_clk is of 100 MHz frequency and you program these bits as 1010, then the resultant MDC clock is of 12.5 MHz which is outside the limit of IEEE 802.3 specified range. Only use the values larger than 7 if the interfacing chips support faster MDC clocks.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>l3_sp_clk 60-100Mhz and MDC clock = l3_sp_clk/42</td> </tr> <tr> <td>0x1</td> <td>l3_sp_clk 100-150Mhz and MDC clock = l3_sp_clk/62</td> </tr> <tr> <td>0x2</td> <td>l3_sp_clk 25-35Mhz and MDC clock = l3_sp_clk/16</td> </tr> <tr> <td>0x3</td> <td>l3_sp_clk 35-60Mhz and MDC clock = l3_sp_clk/26</td> </tr> <tr> <td>0x4</td> <td>l3_sp_clk 150-250Mhz and MDC clock = l3_sp_clk/102</td> </tr> <tr> <td>0x5</td> <td>l3_sp_clk 250-300Mhz and MDC clock = l3_sp_clk/124</td> </tr> <tr> <td>0x8</td> <td>l3_sp_clk/4</td> </tr> <tr> <td>0x9</td> <td>l3_sp_clk/6</td> </tr> <tr> <td>0xa</td> <td>l3_sp_clk/8</td> </tr> <tr> <td>0xb</td> <td>l3_sp_clk/10</td> </tr> <tr> <td>0xc</td> <td>l3_sp_clk/12</td> </tr> <tr> <td>0xd</td> <td>l3_sp_clk/14</td> </tr> <tr> <td>0xe</td> <td>l3_sp_clk/16</td> </tr> <tr> <td>0xf</td> <td>l3_sp_clk/18</td> </tr> </tbody> </table>	Value	Description	0x0	l3_sp_clk 60-100Mhz and MDC clock = l3_sp_clk/42	0x1	l3_sp_clk 100-150Mhz and MDC clock = l3_sp_clk/62	0x2	l3_sp_clk 25-35Mhz and MDC clock = l3_sp_clk/16	0x3	l3_sp_clk 35-60Mhz and MDC clock = l3_sp_clk/26	0x4	l3_sp_clk 150-250Mhz and MDC clock = l3_sp_clk/102	0x5	l3_sp_clk 250-300Mhz and MDC clock = l3_sp_clk/124	0x8	l3_sp_clk/4	0x9	l3_sp_clk/6	0xa	l3_sp_clk/8	0xb	l3_sp_clk/10	0xc	l3_sp_clk/12	0xd	l3_sp_clk/14	0xe	l3_sp_clk/16	0xf	l3_sp_clk/18	RW	0x0

GMII_Data Fields

Bit	Name	Description	Access	Reset
15:0	gd	This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation.	RW	0x0

Flow_Control

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control block. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

1	tfe	<p>In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames. In half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back-pressure feature is disabled.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Transmit Flow Control Disable</td> </tr> <tr> <td>0x1</td> <td>Transmit Flow Control Enable</td> </tr> </tbody> </table>	Value	Description	0x0	Transmit Flow Control Disable	0x1	Transmit Flow Control Enable	RW	0x0
Value	Description									
0x0	Transmit Flow Control Disable									
0x1	Transmit Flow Control Enable									

Bit	Name	Description	Access	Reset						
0	fca_bpa	<p>This bit initiates a Pause Control frame in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. In the full-duplex mode, this bit should be read as 1'b0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1'b1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared. In the half-duplex mode, when this bit is set (and TFE is set), then backpressure is asserted by the MAC. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Pause Ctrl Frame and BPA off</td> </tr> <tr> <td>0x1</td> <td>Init Pause Ctrl Frame and BPA</td> </tr> </tbody> </table>	Value	Description	0x0	Pause Ctrl Frame and BPA off	0x1	Init Pause Ctrl Frame and BPA	RW	0x0
Value	Description									
0x0	Pause Ctrl Frame and BPA off									
0x1	Init Pause Ctrl Frame and BPA									

VLAN_Tag

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. Because the VLAN Tag register is double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

VLAN_Tag Fields

Bit	Name	Description	Access	Reset						
19	vthm	When set, the most significant four bits of the VLAN tag's CRC are used to index the content of Register 354 (VLAN Hash Table Register). A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. When reset, the VLAN Hash Match operation is not performed.	RW	0x0						
18	esvl	When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.	RW	0x0						
17	vtim	When set, this bit enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The frames with matched VLAN Tag are marked as matched.	RW	0x0						
16	etv	When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Disable 12-Bit VLAN Tag Compare</td> </tr> <tr> <td>0x1</td> <td>Enable 12-Bit VLAN Tag Compare</td> </tr> </tbody> </table>	Value	Description	0x0	Disable 12-Bit VLAN Tag Compare	0x1	Enable 12-Bit VLAN Tag Compare	RW	0x0
Value	Description									
0x0	Disable 12-Bit VLAN Tag Compare									
0x1	Enable 12-Bit VLAN Tag Compare									

Bit	Name	Description	Access	Reset
15:0	v1	This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field: * Bits [15:13]: User Priority * Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) * Bits[11:0]: VLAN tag's VLAN Identifier (VID) field When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88a8 as VLAN frames.	RW	0x0

Version

The Version registers identifies the version of the EMAC. This register contains two bytes: one specified by Synopsys to identify the core release number, and the other specified by Altera.

Module Instance	Base Address	Register Address

LPI_Control_Status Fields

Bit	Name	Description	Access	Reset						
19	lpitxa	<p>This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the transmit side. This bit is not functional in the GMAC-CORE configuration in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding frames (in the core) and pending frames (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any frame for transmission or the application issues a TX FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If TX FIFO Flush is set, in Bit 20 of Register 6 (Operation Mode Register), when the MAC is in the LPI mode, the MAC exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>LPI TX Automate Disabled</td> </tr> <tr> <td>0x1</td> <td>LPI TX Automate Enabled</td> </tr> </tbody> </table>	Value	Description	0x0	LPI TX Automate Disabled	0x1	LPI TX Automate Enabled	RW	0x0

LPI_Timers_Control Fields

Bit	Name	Description	Access	Reset
25:16	1st	This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.	RW	0x3E8
15:0	tw	This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.	RW	0x0

Interrupt_Status

The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding optional feature is enabled.

Module Instance	Base Address	Register Address

0x1	RGMII or SMII Interrupt Mask Enable									

MAC_Address0_High

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. Because the MAC address registers are double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700040
emac1	0xFF702000	0xFF702040

Offset: 0x40

MAC_Address0_Low Fields

Bit	Name	Description	Access	Reset
31:0	addrlo	This field contains the lower 32 bits of the first 6-byte MAC address. This is used by the MAC for filtering the received frames and inserting the MAC address in the Transmit Flow Control (PAUSE) Frames.	RW	0xFFFFFFFF FFF

MAC_Address1_High

The MAC Address1 High register holds the upper 16 bits of the 2nd 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address4 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address7_High

The MAC Address7 High register holds the upper 16 bits of the 8th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address7 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 13th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address13_High

The MAC Address13 High register holds the upper 16 bits of the 14th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address13 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address14_Low Fields

Bit	Name	Description	Access	Reset
31:0	addrlo	This field contains the lower 32 bits of the 15th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address15_High

The MAC Address15 High register holds the upper 16 bits of the 16th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address15 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MMC_Control

The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

This bit is cleared automatically after one clock cycle.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Auto cleared after 1 clock cycle</td> </tr> <tr> <td>0x1</td> <td>All Counters Reset</td> </tr> </tbody> </table>	Value	Description	0x0	Auto cleared after 1 clock cycle	0x1	All Counters Reset	RW	0x0
Value	Description									
0x0	Auto cleared after 1 clock cycle									
0x1	All Counters Reset									

MMC_Receive_Interrupt

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

MMC_Transmit_Interrupt

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and the maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700108
emac1	0xFF702000	0xFF702108

Offset: 0x108

MMC_IPC_Receive_Interrupt

This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

L3_L4_Control0 Fields

Bit	Name	Description	Access	Reset
21	14dpim0	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 20 (L4DPM0) is set high.	RW	0x0
20	14dpm0	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Destination Port number field for matching.	RW	0x0
19	14spim0	When set, this bit indicates that the Layer 4 Source Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 18 (L4SPM0) is set high.	RW	0x0
18	14spm0	When set, this bit indicates that the Layer 4 Source Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Source Port number field for matching.	RW	0x0
16	14pen0	When set, this bit indicates that the Source and Destination Port number fields for UDP frames are used for matching. When reset, this bit indicates that the Source and Destination Port number fields for TCP frames are used for matching. The Layer 4 matching is done only when either L4SPM0 or L4DPM0 bit is set high.	RW	0x0

Bit	Name	Description	Access	Reset
15:11	l3hdbm0	IPv4 Frames: This field contains the number of higher bits of IP Destination Address that are masked in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: Bits [12:11] of this field correspond to Bits [6:5] of L3HSBM0, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 frames. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 127: All bits except MSb are masked. This field is valid and applicable only if L3DAM0 or L3SAM0 is set high.	RW	0x0
10:6	l3hsbm0	IPv4 Frames: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: This field contains Bits [4:0] of the field that indicates the number of higher bits of IP Source or Destination Address matched in the IPv6 frames. This field is valid and applicable only if L3DAM0 or L3SAM0 is set high.	RW	0x0
5	l3daim0	When set, this bit indicates that the Layer 3 IP Destination Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 4 (L3DAM0) is set high.	RW	0x0
4	l3dam0	When set, this bit indicates that Layer 3 IP Destination Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When Bit 0 (L3PEN0) is set, you should set either this bit or Bit 2 (L3SAM0) because either IPv6 DA or SA can be checked for filtering.	RW	0x0
3	l3saim0	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 2 (L3SAM0) is set high.	RW	0x0

Bit	Name	Description	Access	Reset
2	l3sam0	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN0) is set, you should set either this bit or Bit 4 (L3DAM0) because either IPv6 SA or DA can be checked for filtering.	RW	0x0
0	l3pen0	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM0 or L3DAM0 bit is set high.	RW	0x0

Layer4_Address0

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: Bits [12:11] of this field correspond to Bits [6:5] of L3HSBM3, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 frames. The following list describes the concatenated values of the L3HDBM3[1:0] and L3HSBM3 bits: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 127: All bits except MSb are masked. This field is valid and applicable only if L3DAM3 or L3SAM3 is set high.	RW	0x0

Bit	Name	Description	Access	Reset
10:6	l3hsbm3	IPv4 Frames: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: This field contains Bits [4:0] of the field that indicates the number of higher bits of IP Source or Destination Address matched in the IPv6 frames. This field is valid and applicable only if L3DAM3 or L3SAM3 is set high.	RW	0x0
5	l3daim3	When set, this bit indicates that the Layer 3 IP Destination Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 4 (L3DAM3) is set high.	RW	0x0
4	l3dam3	When set, this bit indicates that Layer 3 IP Destination Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When Bit 0 (L3PEN3) is set, you should set either this bit or Bit 2 (L3SAM3) because either IPv6 DA or SA can be checked for filtering.	RW	0x0
3	l3saim3	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 2 (L3SAM3) is set high.	RW	0x0
2	l3sam3	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN3) is set, you should set either this bit or Bit 4 (L3DAM3) because either IPv6 SA or DA can be checked for filtering.	RW	0x0
0	l3pen3	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM3 or L3DAM3 bit is set high.	RW	0x0

Layer4_Address3

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr3_Reg3 Fields

Bit	Name	Description	Access	Reset
31:0	13a33	When Bit 0 (L3PEN3) and Bit 2 (L3SAM3) are set in Register 292 (Layer 3 and Layer 4 Control Register 3), this field contains the value to be matched with Bits [127:96] of the IP Source Address field in the IPv6 frames. When Bit 0 (L3PEN3) and Bit 4 (L3DAM3) are set in Register 292 (Layer 3 and Layer 4 Control Register 3), this field contains the value to be matched with Bits [127:96] of the IP Destination Address field in the IPv6 frames. When Bit 0 (L3PEN3) is reset in Register 292 (Layer 3 and Layer 4 Control Register 3), this register is not used.	RW	0x0

Hash_Table_Reg0

This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper 8 bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

VLAN_Hash_Table_Reg

The 16-bit Hash table is used for group address filtering based on VLAN tag when Bit 18 (VTHM) of Register 7 (VLAN Tag Register) is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on Bit 16 (ETV) of VLAN Tag Register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper four bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. Notes: * Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Sub_Second_Increment

In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of `clk_ptp_ref_i`. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

Module Instance	Base Address	Register Address

Sub_Second_Increment Fields

Bit	Name	Description	Access	Reset
7:0	ssinc	The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (0x2B) that is derived by 20ns/0.465.	RW	0x0

System_Time_Seconds

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to l3_sp_clk).

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700708

Target_Time_Nanoseconds Fields

Bit	Name	Description	Access	Reset
31	trgtbusy	The MAC sets this bit when the PPSCMD field (Bits[3:0]) in Register 459 (PPS Control Register) is programmed to 010 or 011. Programming the PPSCMD field to 010 or 011, instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain. The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. This bit is reserved when the Enable Flexible Pulse-Per-Second Output feature is not selected.	RO	0x0
30:0	ttslo	This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the both Target Timestamp registers, then based on the TRGTMODSELO field (Bits [6:5]) in Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when TSCTRLSSR is set in the Timestamp control register. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.	RW	0x0

0x2	Target Time gen. interr event and sig pps0											
0x3	Target Time No inter just start and stop sig pps0											
4	ppsen0	<p>When set low, Bits[3:0] function as PPSCMD (backward compatible). When set high, Bits[3:0] function as PPSCMD.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Bits[3:0] function as ppsctrl0</td> </tr> <tr> <td>0x1</td> <td>Bits[3:0] function as ppscmd</td> </tr> </tbody> </table>	Value	Description	0x0	Bits[3:0] function as ppsctrl0	0x1	Bits[3:0] function as ppscmd	RW	0x0		
Value	Description											
0x0	Bits[3:0] function as ppsctrl0											
0x1	Bits[3:0] function as ppscmd											
3:0	ppsctrl0_ppscmd	<p>PPSCMD0: PPS0 Output Frequency Control</p> <p>This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCMD is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCMD, the PPS output becomes a generated clock of following frequencies:</p> <ul style="list-style-type: none"> -0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. -0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. -0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. -0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. -... -1111: The binary rollover is 32.768 KHz, and the digital rollover is 16.384 KHz. 	RW	0x0								

Bit	Name	Description	Access	Reset
		<p>Note:</p> <p>In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies.</p> <p>In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:</p> <ul style="list-style-type: none"> * When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms * When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of: <ul style="list-style-type: none"> - One clock of 50 percent duty cycle and 537 ms period - Second clock of 463 ms period (268 ms low and 195 ms high) * When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of: <ul style="list-style-type: none"> - Three clocks of 50 percent duty cycle and 268 ms period - Fourth clock of 195 ms period (134 ms low and 61 ms high) <p>This behavior is because of the non-linear toggling of bits in the digital rollover mode in Register 451 (System Time - Nanoseconds Register).</p> <p>Flexible PPS0 Output (ptp_pps_o[0]) Control</p> <p>Programming these bits with a non-zero value instructs the MAC to initiate an event. Once the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The Software should ensure that these bits are programmed only when they are all-zero. The following list describes the values of PPSCMD0:</p> <ul style="list-style-type: none"> * 0000: No Command * 0001: START Single Pulse <p>This command generates single pulse</p>		

Bit	Name	Description	Access	Reset
		<p>rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register.</p> <ul style="list-style-type: none"> * 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. * 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. * 0100: STOP Pulse train at time This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. * 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). * 0110: Cancel STOP Pulse train This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. * 0111-1111: Reserved 		

Auxiliary_Timestamp_Nanoseconds

This register, along with Register 461 (Auxiliary Timestamp Seconds Register), gives the 64-bit timestamp stored as auxiliary snapshot. The two registers together form the read port of a 64-bit wide FIFO with a depth of 16. Multiple snapshots can be stored in this FIFO. The ATSNS bits in the Timestamp Status register indicate the fill-level of this FIFO. The top of the FIFO is removed only when the last byte of Register 461 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read. In big-endian mode, it corresponds to the reading of Bits[7:0] of Register 461 (Auxiliary Timestamp - Seconds Register).

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700730

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ppsint RW 0x0															

PPS0_Interval Fields

Bit	Name	Description	Access	Reset
31:0	ppsint	These bits store the interval between the rising edges of PPS0 signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20ns), and desired interval between rising edges of PPS0 signal output is 100ns (that is, five units of sub-second increment value), then you should program value 4 (5 -1) in this register.	RW	0x0

PPS0_Width

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (ptp_pps_o[0]).

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700764
emac1	0xFF702000	0xFF702764

Offset: 0x764

Access: RW

Bit Fields

ppswidth RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ppswidth RW 0x0															

PPS0_Width Fields

Bit	Name	Description	Access	Reset
31:0	ppswidth	These bits store the width between the rising edge and corresponding falling edge of the PPS0 signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20ns), and desired width between the rising and corresponding falling edges of PPS0 signal output is 80ns (that is, four units of sub-second increment value), then you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in Register 472 (PPS0 Interval Register).	RW	0x0

MAC_Address16_High

The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address18_High

The MAC Address18 High register holds the upper 16 bits of the 19th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address18 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 24th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address24_High

The MAC Address24 High register holds the upper 16 bits of the 25th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address24 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address26_High

The MAC Address26 High register holds the upper 16 bits of the 27th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address26 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

The MAC Address34 High register holds the upper 16 bits of the 35th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address34 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address37_High

The MAC Address37 High register holds the upper 16 bits of the 38th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address37 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 43th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address43_High

The MAC Address43 High register holds the upper 16 bits of the 44th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address43 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address45_High

The MAC Address45 High register holds the upper 16 bits of the 46th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address45 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

The MAC Address53 High register holds the upper 16 bits of the 54th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address53 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 62th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address62_High

The MAC Address62 High register holds the upper 16 bits of the 63th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address62 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address64_High

The MAC Address64 High register holds the upper 16 bits of the 65th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address64 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address70_High

The MAC Address70 High register holds the upper 16 bits of the 71th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address70 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

The MAC Address72 High register holds the upper 16 bits of the 73th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address72 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address75_High

The MAC Address75 High register holds the upper 16 bits of the 76th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address75 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 81th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address81_High

The MAC Address81 High register holds the upper 16 bits of the 82th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address81 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address83_High

The MAC Address83 High register holds the upper 16 bits of the 84th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address83 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

The MAC Address91 High register holds the upper 16 bits of the 92th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address91 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address94_High

The MAC Address94 High register holds the upper 16 bits of the 95th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address94 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 100th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address100_High

The MAC Address100 High register holds the upper 16 bits of the 101th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address100 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address102_High

The MAC Address102 High register holds the upper 16 bits of the 103th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address102 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address108_High

The MAC Address108 High register holds the upper 16 bits of the 109th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address108 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Bit	Name	Description	Access	Reset
31:0	addrlo	This field contains the lower 32 bits of the 110th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address110_High

The MAC Address110 High register holds the upper 16 bits of the 111th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address110 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address113_High

The MAC Address113 High register holds the upper 16 bits of the 114th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address113 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address119_High

The MAC Address119 High register holds the upper 16 bits of the 120th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address119 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address121_High

The MAC Address121 High register holds the upper 16 bits of the 122th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address121 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address127_High

The MAC Address127 High register holds the upper 16 bits of the 128th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address127 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

DMA Register Group Register Descriptions

DMA Register Group

Offset: 0x1000

[Bus_Mode](#) on page 17-820

The Bus Mode register establishes the bus operating modes for the DMA.

[Transmit_Poll_Demand](#) on page 17-823

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

[Receive_Poll_Demand](#) on page 17-824

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

[Receive_Descriptor_List_Address](#) on page 17-825

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Transmit_Descriptor_List_Address on page 17-826

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Status on page 17-826

The Status register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

Operation_Mode on page 17-832

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

Interrupt_Enable on page 17-838

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Missed_Frame_And_Buffer_Overflow_Counter on page 17-842

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Receive_Interrupt_Watchdog_Timer on page 17-843

This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)

AXI_Bus_Mode on page 17-844

The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

AHB_or_AXI_Status on page 17-847

This register provides the active status of the AXI interface's read and write channels. This register is useful for debugging purposes.

Current_Host_Transmit_Descriptor on page 17-848

The Current Host Transmit Descriptor register points to the start address of the current Transmit Descriptor read by the DMA.

Current_Host_Receive_Descriptor on page 17-848

The Current Host Receive Descriptor register points to the start address of the current Receive Descriptor read by the DMA.

Current_Host_Transmit_Buffer_Address on page 17-849

The Current Host Transmit Buffer Address register points to the current Transmit Buffer Address being read by the DMA.

Current_Host_Receive_Buffer_Address on page 17-849

The Current Host Receive Buffer Address register points to the current Receive Buffer address being read by the DMA.

HW_Feature on page 17-850

This register indicates the presence of the optional features or functions of the gmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bus_Mode

The Bus Mode register establishes the bus operating modes for the DMA.

Bit	Name	Description	Access	Reset						
16	fb	<p>This bit controls whether the AXI Master interface performs fixed burst transfers or not. When set, the AXI interface uses FIXED bursts during the start of the normal burst transfers. When reset, the AXI interface uses SINGLE and INCR burst transfer operations. For more information, see Bit 0 (UNDEFINED) of the AXI Bus Mode register.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>SINGLE or INCR Burst</td> </tr> <tr> <td>0x1</td> <td>FIXED Burst (1, 4, 8, or 16)</td> </tr> </tbody> </table>	Value	Description	0x0	SINGLE or INCR Burst	0x1	FIXED Burst (1, 4, 8, or 16)	RW	0x0
Value	Description									
0x0	SINGLE or INCR Burst									
0x1	FIXED Burst (1, 4, 8, or 16)									
13:8	pbl	<p>These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable only for Tx DMA transactions. If the number of beats to be transferred is more than 32, then perform the following steps: 1. Set the 8xPBL mode. 2. Set the PBL. For example, if the maximum number of beats to be transferred is 64, then first set 8xPBL to 1 and then set PBL to 8. The PBL values have the following limitation: The maximum number of possible beats (PBL) is limited by the size of the Tx FIFO and Rx FIFO in the MTL layer and the data bus width on the DMA. The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO, except when specified.</p>	RW	0x1						
7	atds	<p>When set, the size of the alternate (enhanced) descriptor increases to 32 bytes (8 DWORDS). When clear, the alternate (enhanced) descriptor size is 16 bytes (4 DWORDS).</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Descriptor size is 16 bytes (4 DWORDS)</td> </tr> <tr> <td>0x1</td> <td>Descriptor size is 32 bytes (8 DWORDS)</td> </tr> </tbody> </table>	Value	Description	0x0	Descriptor size is 16 bytes (4 DWORDS)	0x1	Descriptor size is 32 bytes (8 DWORDS)	RW	0x0
Value	Description									
0x0	Descriptor size is 16 bytes (4 DWORDS)									
0x1	Descriptor size is 32 bytes (8 DWORDS)									

Bit	Name	Description	Access	Reset						
6:2	dsl	This bit specifies the number of Word, Dword, or Lword (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When the DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA in Ring mode.	RW	0x0						
0	swr	<p>When this bit is set, the MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the EMAC clock domains. Before reprogramming any register of the EMAC, you should read a zero (0) value in this bit . Note: * The Software reset function is driven only by this bit. * The reset operation is completed only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for the software reset completion.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>MAC DMA Controller Clears Logic</td> </tr> <tr> <td>0x1</td> <td>MAC DMA Controller Resets Logic</td> </tr> </tbody> </table>	Value	Description	0x0	MAC DMA Controller Clears Logic	0x1	MAC DMA Controller Resets Logic	RW	0x1
Value	Description									
0x0	MAC DMA Controller Clears Logic									
0x1	MAC DMA Controller Resets Logic									

Transmit_Poll_Demand

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

Transmit_Poll_Demand Fields

Bit	Name	Description	Access	Reset
31:0	tpd	When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 18 (Current Host Transmit Descriptor Register). If that descriptor is not available (owned by the Host), the transmission returns to the Suspend state and the Bit 2 (TU) of Register 5 (Status Register) is asserted. If the descriptor is available, the transmission resumes.	RW	0x0

Receive_Poll_Demand

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

Receive_Poll_Demand Fields

Bit	Name	Description	Access	Reset
31:0	rpd	When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 19 (Current Host Receive Descriptor Register). If that descriptor is not available (owned by the Host), the reception returns to the Suspended state and the Bit 7 (RU) of Register 5 (Status Register) is not asserted. If the descriptor is available, the Rx DMA returns to the active state.	RW	0x0

Receive_Descriptor_List_Address

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Receive_Descriptor_List_Address Fields

Bit	Name	Description	Access	Reset
31:2	rdesla_32bit	This field contains the base address of the first descriptor in the Receive Descriptor list. The LSB bits (1:0) are ignored (32-bit wide bus) and internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).	RW	0x0

Transmit_Descriptor_List_Address

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

31:2	tdesla_32bit	This field contains the base address of the first descriptor in the Transmit Descriptor list. The LSB bits (1:0) are ignored (32-bit wide bus) and are internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).	RW	0x0

Status

The Status register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to

be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

Bit	Name	Description	Access	Reset
16	nis	Normal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[0]: Transmit Interrupt * Register 5[2]: Transmit Buffer Unavailable * Register 5[6]: Receive Interrupt * Register 5[14]: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in Register 7) affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing 1 to this bit) each time a corresponding bit, which causes NIS to be set, is cleared.	RW	0x0
15	ais	Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[1]: Transmit Process Stopped * Register 5[3]: Transmit Jabber Timeout * Register 5[4]: Receive FIFO Overflow * Register 5[5]: Transmit Underflow * Register 5[7]: Receive Buffer Unavailable * Register 5[8]: Receive Process Stopped * Register 5[9]: Receive Watchdog Timeout * Register 5[10]: Early Transmit Interrupt * Register 5[13]: Fatal Bus Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit, which causes AIS to be set, is cleared.	RW	0x0
14	eri	This bit indicates that the DMA had filled the first data buffer of the packet. Bit 6 (RI) of this register automatically clears this bit.	RW	0x0
13	fbi	This bit indicates that a bus error occurred, as described in Bits[25:23]. When this bit is set, the corresponding DMA engine disables all of its bus accesses.	RW	0x0
10	eti	This bit indicates that the frame to be transmitted is fully transferred to the MTL Transmit FIFO.	RW	0x0
9	rwt	This bit is asserted when a frame with length greater than 2,048 bytes is received (10,240 when Jumbo Frame mode is enabled).	RW	0x0
8	rps	This bit is asserted when the Receive Process enters the Stopped state.	RW	0x0

Bit	Name	Description	Access	Reset
7	ru	This bit indicates that the host owns the Next Descriptor in the Receive List and the DMA cannot acquire it. The Receive Process is suspended. To resume processing Receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, the Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor is owned by the DMA.	RW	0x0
6	ri	This bit indicates that the frame reception is complete. When reception is complete, the Bit 31 of RDES1 (Disable Interrupt on Completion) is reset in the last Descriptor, and the specific frame status information is updated in the descriptor. The reception remains in the Running state.	RW	0x0
5	unf	This bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.	RW	0x0
4	ovf	This bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].	RW	0x0
3	tjt	This bit indicates that the Transmit Jabber Timer expired, which happens when the frame size exceeds 2,048 (10,240 bytes when the Jumbo frame is enabled) . When the Jabber Timeout occurs, the transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.	RW	0x0
2	tu	This bit indicates that the host owns the Next Descriptor in the Transmit List and the DMA cannot acquire it. Transmission is suspended. Bits[22:20] explain the Transmit Process state transitions. To resume processing Transmit descriptors, the host should change the ownership of the descriptor by setting TDES0[31] and then issue a Transmit Poll Demand command.	RW	0x0
1	tps	This bit is set when the transmission is stopped.	RW	0x0

Bit	Name	Description	Access	Reset
0	ti	This bit indicates that the frame transmission is complete. When transmission is complete, the Bit 31 (Interrupt on Completion) of TDES1 is reset in the first descriptor, and the specific frame status information is updated in the descriptor.	RW	0x0

Operation_Mode

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

0x1	Tx Start with Full Frame									

Bit	Name	Description	Access	Reset																		
20	ftf	<p>When this bit is set, the transmit FIFO controller logic is reset to its default values and thus all data in the Tx FIFO is lost or flushed. This bit is cleared internally when the flushing operation is completed. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation is complete only when the Tx FIFO is emptied of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. To complete this flush operation, the PHY transmit clock is required to be active.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Tx FIFO Data not Flushed</td> </tr> <tr> <td>0x1</td> <td>TX FIFO Data Flushed</td> </tr> </tbody> </table>	Value	Description	0x0	Tx FIFO Data not Flushed	0x1	TX FIFO Data Flushed	RW	0x0

Bit	Name	Description	Access	Reset										
13	st	<p>When this bit is set, transmission is placed in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Register 4 (Transmit Descriptor List Address Register), or from the position retained when transmission was stopped previously. If the DMA does not own the current descriptor, transmission enters the Suspended state and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting Register 4 (Transmit Descriptor List Address Register), then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. To change the list address, you need to program Register 4 (Transmit Descriptor List Address Register) with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Transmission Stopped State</td> </tr> <tr> <td>0x1</td> <td>Transmission in Run State</td> </tr> </tbody> </table>	Value	Description	0x0	Transmission Stopped State	0x1	Transmission in Run State	RW	0x0

Missed_Frame_And_Buffer_Overflow_Counter

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701020
emac1	0xFF702000	0xFF703020

Receive Interrupt Watchdog Timer Fields

Bit	Name	Description	Access	Reset
7:0	riwt	This bit indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame.	RW	0x0

AXI_Bus_Mode

The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

Module Instance	Base Address	Register Address

Document Revision History

Table 17-27: Document Revision History

Date	Version	Changes
May 2015	2015.05.04	<ul style="list-style-type: none"> Corrected IEEE 1588 timestamp resolution in the "EMAC Block Diagram and System Integration" section and the "IEEE 1588-2002 Timestamps" section Added reset pulse width for <code>rst_clk_tx_n_o</code> and <code>rst_clk_rx_n_o</code> in the "FPGA EMAC I/O signals" section Added subsections "Ordinary Clock," "Boundary Clock," "End-to-End Transparent Clock" and "Peer-to-Peer Transparent Clock" in the "Clock Type" section

Date	Version	Changes
December 2014	2014.12.15	<ul style="list-style-type: none"> Updated <i>EMAC Block Diagram and System Integration</i> section with new diagram and information. Added <i>Signal Descriptions</i> section. Added <i>EMAC Internal Interfaces</i> section. Added <i>TX FIFO</i> and <i>RX FIFO</i> subsection to the <i>Transmit and Receive Data FIFO Buffers</i> section. Updated <i>Descriptor Overview</i> section to clarify support for only enhanced (alternate) descriptors. Added <i>Destination and Source Address Filtering Summary</i> in <i>Frame Filtering</i> Section. The hard processor system (HPS) provides two instances of a USB On-The-Go (OTG) controller that supports both device and host functions. The controller supports all high-speed, full-speed, and low-speed transfers in both device and host modes. The controller is fully compliant with the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The controller can be programmed for both device and host functions to support data movement over the USB protocol.

The controllers are operationally independent of each other. Each USB OTG controller supports a single USB port connected through a USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) compliant PHY. The USB OTG controllers are instances of the Synopsys[®] ([†])DesignWare[®] Cores USB 2.0 Hi-Speed On-The-Go (DWC_otg) controller.

The USB OTG controller is optimized for the following applications and systems: †

- Portable electronic devices †
- Point-to-point applications (no hub, direct connection to HS, FS, or LS device) †
- Multi-point applications (as an embedded USB host) to devices (hub and split support) †

Each of the two USB OTG ports supports both host and device modes, as described in the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The USB OTG ports support connections for all types of USB peripherals, including the following peripherals:

- Mouse
- Keyboard
- Digital cameras
- Network adapters
- Hard drives
- Generic hubs

Additional information is available in the On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification, which you can download from the USB Implementers Forum website

Features of the USB OTG Controller

The USB OTG controller has the following USB-specific features:

- Complies with both Revision 1.3 and Revision 2.0 of the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Supports all USB 2.0 speeds:
 - High speed (HS, 480-Mbps)
 - Full speed (FS, 12-Mbps)
 - Low speed (LS, 1.5-Mbps)

Note: In host mode, all speeds are supported. However, in device mode, only high speed and full speed are supported.

- Supports USB 2.0 in ULPI mode
- Supports all USB transaction types:
 - Control transfers
 - Bulk transfers
 - Isochronous transfers
 - Interrupts
- Supports automatic ping capability
- Supports Session Request Protocol (SRP) and Host Negotiation Protocol (HNP)
- Supports suspend, resume, and remote wake
- Supports up to 16 host channels

Note: In host mode, when the number of device endpoints is greater than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.

- Supports up to 16 bidirectional endpoints, including control endpoint 0

Note: Only seven periodic device IN endpoints are supported.

- Supports a generic root hub
- Performs transaction scheduling in hardware

On the USB PHY layer, the USB OTG controller supports the following features:

- A single USB port connected to each OTG instance
- A ULPI connection to an off-chip USB transceiver
- Software-controlled access, supporting vendor-specific or optional PHY registers access to ease debug
- The OTG 2.0 support for Attach Detection Protocol (ADP) only through an external (off-chip) ADP controller

On the integration side, the USB OTG controller supports the following features:

- Different clocks for system and PHY interfaces
- Dedicated TX FIFO buffer for each device IN endpoint in direct memory access (DMA) mode
- Packet-based, dynamic FIFO memory allocation for endpoints for small FIFO buffers and flexible, efficient use of RAM that can be dynamically sized by software
- Ability to change an endpoint's FIFO memory size during transfers
- Clock gating support during USB suspend and session-off modes
 - PHY clock gating support
 - System clock gating support
- Data FIFO RAM clock gating support
- Local buffering with error correction code (ECC) support

Note: The USB OTG controller does not support the following protocols:

- Enhanced Host Controller Interface (EHCI)
- Open Host Controller Interface (OHCI)
- Universal Host Controller Interface (UHCI)

Supported PHYS

The USB OTG controller only supports USB 2.0 ULPI PHYs. Only the single data rate (SDR) mode is supported.

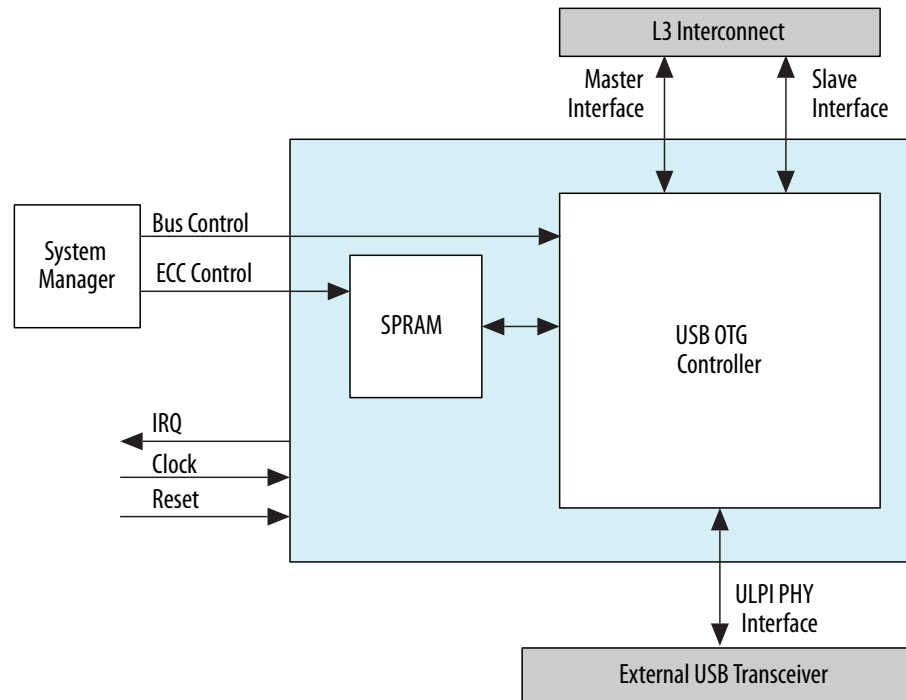

PHYs that support LPM mode may not function properly with the USB controller due to a timing issue. It is recommended that designers use the MicroChip USB3300 PHY device that has been proven to be successful on the development board.

Refer to the *Cyclone V Device Datasheet* for specific timing information.

USB OTG Controller Block Diagram and System Integration

Figure 18-1: USB OTG Controller System Integration

Two subsystems are included in the HPS.

The USB OTG controller connects to the level 3 (L3) interconnect through a slave interface, allowing other masters to access the control and status registers (CSRs) in the controller. The controller also connects to the L3 interconnect through a master interface, allowing the DMA engine in the controller to move data between external memory and the controller.

A single-port RAM (SPRAM) connected to the USB OTG controller is used to store USB data packets for both host and device modes. It is configured as FIFO buffers for receive and transmit data packets on the USB link.

Through the system manager, the USB OTG controller has control to use and test error correction codes (ECCs) in the SPRAM. Through the system manager, the USB OTG controller can also control the behavior of the master interface to the L3 interconnect.

The USB OTG controller connects to the external USB transceiver through a ULPI PHY interface. This interface also connects through pin multiplexers within the HPS. The pin multiplexers are controlled by the system manager.

Additional connections on the USB OTG controller include:

- Clock input from the clock manager to the USB OTG controller
- Reset input from the reset manager to the USB OTG controller
- Interrupt line from the USB OTG controller to the microprocessor unit (MPU) global interrupt controller (GIC).

The USB controller will only use Direct Shared IO 48.

Functional Description of the USB OTG Controller

USB OTG Controller Block Description

Figure 18-2: USB OTG Controller Block Description

Details about each of the units that comprise the USB OTG controller are shown below.

Master Interface

The master interface includes a built-in DMA controller. The DMA controller moves data between external memory and the media access controller (MAC).

Properties of the master interface are controlled through the USB L3 Master HPROT Register (`l3master`) in the system manager. These bits provide access information to the L3 interconnect, including whether or not transactions are cacheable, bufferable, or privileged.

Note: Bits in the `l3master` register can be updated only when the master interface is guaranteed to be in an inactive state.

Slave Interface

The slave interface allows other masters in the system to access the USB OTG controller's CSRs. For testing purposes, other masters can also access the SPRAM.

Slave Interface CSR Unit

The slave interface can read from and write to all the CSRs in the USB OTG controllers. All register accesses are 32 bits.

The CSR is divided into the following groups of registers:

- Global
- Host
- Device
- Power and clock gating

Some registers are shared between host and device modes, because the controller can only be in one mode at a time. The controller generates a mode mismatch interrupt if a master attempts to access device registers when the controller is in host mode, or attempts to access host registers when the controller is in device mode. Writing to unimplemented registers is ignored. Reading from unimplemented registers returns indeterminate values.

Application Interface Unit

The application interface unit (AIU) generates DMA requests based on programmable FIFO buffer thresholds. The AIU generates interrupts to the GIC for both host and device modes. A DMA scheduler is included in the AIU to arbitrate and control the data transfer between packets in system memory and their respective USB endpoints.

Packet FIFO Controller

The Packet FIFO Controller (PFC) connects the AIU with the MAC through data FIFO buffers located in the SPRAM. In device mode, one FIFO buffer is implemented for each IN endpoint. In host mode, a single FIFO buffer stores data for all periodic (isochronous and interrupt) OUT endpoints, and a single FIFO buffer is used for nonperiodic (control and bulk) OUT endpoints. Host and device mode share a single receive data FIFO buffer.

SPRAM

An SPRAM implements the data FIFO buffers for host and device modes. The size of the FIFO buffers can be programmed dynamically.

The SPRAM supports ECCs. ECCs can be enabled through the system manager, by setting the RAM ECC Enable (`en`) bit in the USB0 or USB1 RAM ECC Enable Register (`usb0` or `usb1`), in the ECC Management Register Group (`eccgrp`). Single-bit and double-bit errors in each USB instance can be injected using this register.

The SPRAM provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected), and when double-bit (uncorrectable) errors are detected. The system manager generates an interrupt to the GIC when an ECC error is detected.

MAC

The MAC module implements the following functionality:

- USB transaction support
- Host protocol support
- Device protocol support
- OTG protocol support
- Link power management (LPM) functions

USB Transactions

In device mode, the MAC decodes and checks the integrity of all token packets. For valid OUT or SETUP tokens, the following DATA packet is also checked. If the data packet is valid, the MAC performs the following steps:

1. Writes the data to the receive FIFO buffer
2. Sends the appropriate handshake when required to the USB host

If a receive FIFO buffer is not available, the MAC sends a NAK response to the host. The MAC also supports ping protocol.

For IN tokens, if data is available in the transmit FIFO buffer, the MAC performs the following steps:

1. Reads the data from the FIFO buffer
2. Forms the data packet
3. Transmits the packet to the host
4. Receives the response from the host
5. Sends the updated status to the PFC

In host mode, the MAC receives a token request from the AIU. The MAC performs the following steps:

1. Builds the token packet
2. Sends the packet to the device

For OUT or SETUP transactions, the MAC also performs the following steps:

1. Reads the data from the transmit FIFO buffer
2. Assembles the data packet
3. Sends the packet to the device
4. Waits for a response

The response from the device causes the MAC to send a status update to the AIU.

For IN or PING transactions, the MAC waits for the data or handshake response from the device. For data responses, the MAC performs the following steps:

1. Validates the data
2. Writes the data to the receive FIFO buffer
3. Sends a status update to the AIU
4. Sends a handshake to the device, if appropriate

Host Protocol

In host mode, the MAC performs the following functions:

- Detects connect, disconnect, and remote wakeup events on the USB link
- Initiates reset
- Initiates speed enumeration processes
- Generates Start of Frame (SOF) packets.

Device Protocol

In device mode, the MAC performs the following functions:

- Handles USB reset sequence
- Handles speed enumeration
- Detects USB suspend and resume activity on the USB link
- Initiates remote wakeup
- Decodes SOF packets

OTG Protocol

The MAC handles HNP and SRP for OTG operation. HNP provides a mechanism for swapping host and device roles. SRP provides mechanisms for the host to turn off V_{BUS} to save power, and for a device to request a new USB session.

LPM Functions

The USB OTG controller supports LPM in both host and device modes. With this feature, the USB OTG controller can enter a sleep state when a successful LPM transaction occurs on the USB link.

Wakeup and Power Control

To reduce power, the USB OTG controller supports a power-down mode. In power-down mode, the controller and the PHY can shut down their clocks. The controller supports wakeup on the detection of the following events:

- Resume
- Remote wakeup
- Session request protocol
- New session start

PHY Interface Unit

The USB OTG controller supports synchronous SDR data transmission to a ULPI PHY. The SDR mode implements an eight-bit data bus.

ULPI PHY Interface

Table 18-1: ULPI PHY Interfaces

The ULPI PHY interface is synchronous to the `ulpi_clk` signal coming from the PHY.

Port Name	Bit Width	Direction	Description
<code>ulpi_clk</code>	1	Input	ULPI Clock Receives the 60-MHz clock supplied by the high-speed ULPI PHY. All signals are synchronous to the positive edge of the clock.
<code>ulpi_dir</code>	1	Input	ULPI Data Bus Control 1—The PHY has data to transfer to the USB OTG controller. 0—The PHY does not have data to transfer.
<code>ulpi_nxt</code>	1	Input	ULPI Next Data Control Indicates that the PHY has accepted the current byte from the USB OTG controller. When the PHY is transmitting, this signal indicates that a new byte is available for the controller.
<code>ulpi_stp</code>	1	Output	ULPI Stop Data Control The controller drives this signal high to indicate the end of its data stream. The controller can also drive this signal high to request data from the PHY.
<code>ulpi_data[7:0]</code>	8	Bidirectional	Bidirectional data bus. Driven low by the controller during idle.

Local Memory Buffer

The NAND flash controller has three local SRAM memory buffers.

- The write FIFO buffer is a 128 × 32-bit memory (512 total bytes)
- The read FIFO buffer is a 32 × 32-bit memory (128 total bytes)
- The ECC buffer is a 96 × 16-bit memory (1536 total bytes)

The SPRAM is a 8192 × 35-bit (32 data bits and 3 control bits) memory and includes support for ECC (Error Checking and Correction). The ECC block is integrated around a memory wrapper. It provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single- and double-bit errors for test purposes. The ECC feature is disabled by default. It must be initialized to enable the ECC function.

Clocks

Table 18-2: USB OTG Controller Clock Inputs

All clocks must be operational when reset is released. No special handling is required on the clocks.

Clock Signal	Frequency	Functional Usage
usb_mp_clk	60 – 200 MHz	Drives the master and slave interfaces, DMA controller, and internal FIFO buffers
usb0_ulpi_clk	60 MHz	ULPI reference clock for usb0 from external ULPI PHY I/O pin
usb1_ulpi_clk	60 MHz	ULPI reference clock for usb1 from external ULPI PHY I/O pin

Resets

The USB OTG controller can be reset either through the hardware reset input or through software.

Reset Requirements

There must be a minimum of 12 cycles on the `ulpi_clk` clock before the controller is taken out of reset. During reset, the USB OTG controller asserts the `ulpi_stp` signal. The PHY outputs a clock when it sees the `ulpi_stp` signal asserted. However, if the pin multiplexers are not programmed, the PHY does not see the `ulpi_stp` signal. As a result, the `ulpi_clk` clock signal does not arrive at the USB OTG controller.

Software must ensure that the reset is active for a minimum of two `usb_mp_clk` cycles. There is no maximum assertion time.

Hardware Reset

Each of the USB OTG controllers has one reset input from the reset manager. The reset signal is asserted during a cold or warm reset event. The reset manager holds the controllers in reset until software releases the resets. Software releases resets by clearing the appropriate USB bits in the Peripheral Module Reset Register (`permodrst`) in the HPS reset manager.

The reset input resets the following blocks:

- The master and slave interface logic
- The integrated DMA controller
- The internal FIFO buffers
- The CSR

The reset input is synchronized to the `usb_mp_clk` domain. The reset input is also synchronized to the ULPI clock within the USB OTG controller and is used to reset the ULPI PHY domain logic.

Software Reset

Software can reset the controller by setting the Core Soft Reset (`csftrst`) bit in the Reset Register (`grstctl`) in the Global Registers (`globgrp`) group of the USB OTG controller.

Software resets are useful in the following situations:

- A PHY selection bit is changed by software. Resetting the USB OTG controller is part of clean-up to ensure that the PHY can operate with the new configuration or clock.
- During software development and debugging.

Taking the USB 2.0 OTG Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

[Modules Requiring Software Deassert](#) on page 3-9

Interrupts

Table 18-3: USB OTG Interrupt Conditions

Each USB OTG controller has a single interrupt output. Interrupts are asserted on the conditions shown in the following table.

Condition	Mode
Device-initiated remote wakeup is detected.	Host mode
Session request is detected from the device.	Host mode
Device disconnect is detected.	Host mode
Host LPM entry retry has expired or LPM transaction(s) are complete.	Host mode
Host periodic TX FIFO buffer is empty (can be further programmed to indicate half-empty).	Host mode
Host channels interrupt received.	Host mode
Incomplete periodic transfer is pending at the end of the microframe.	Host mode
Host port status interrupt received.	Host mode
External host initiated resume is detected.	Device mode
LPM handshake is sent.	Device mode
Reset is detected when in suspend or normal mode.	Device mode
USB suspend mode is detected.	Device mode

Condition	Mode
Data fetch is suspended due to TX FIFO buffer full or request queue full.	Device mode
At least one isochronous OUT endpoint is pending at the end of the microframe.	Device mode
At least one isochronous IN endpoint is pending at the end of the microframe.	Device mode
At least one IN or OUT endpoint interrupt is pending at the end of the microframe.	Device mode
The end of the periodic frame is reached.	Device mode
Failure to write an isochronous OUT packet to the RX FIFO buffer. The RX FIFO buffer does not have enough space to accommodate the maximum packet size for the isochronous OUT endpoint.	Device mode
Enumeration has completed.	Device mode
Connector ID change.	Common modes
Mode mismatch. Software accesses registers belonging to an incorrect mode.	Common modes
Nonperiodic TX FIFO buffer is empty.	Common modes
RX FIFO buffer is not empty.	Common modes
Start of microframe.	Common modes
Device connection debounce is complete in host mode.	OTG interrupts
A-Device timeout while waiting for B-Device connection.	OTG interrupts
Host negotiation is complete.	OTG interrupts
Session request is complete.	OTG interrupts
Session end is detected in device mode.	OTG interrupts

USB OTG Controller Programming Model

For detailed information about using the USB OTG controller, consult your operating system (OS) driver documentation. The OS vendor provides application programming interfaces (APIs) to control USB host, device and OTG operation. This section provides a brief overview of the following software operations:

- Enabling SPRAM ECCs
- Host operation
- Device operation

Enabling SPRAM ECCs

To avoid false ECC errors, you must initialize the ECC bits in the SPRAM before using ECCs. To initialize the ECC bits, software writes data to all locations in the SPRAM.

The L3 interconnect has access to the SPRAM and is accessible through the USB OTG L3 slave interface. Software accesses the SPRAM through the `directfifo` memory space, in the USB OTG controller address space.

The SPRAM contains 8192 (32 KB) locations. The L3 slave provides 32-bit access to the SPRAM. Physically, the SPRAM is implemented as a 35-bit memory, with the highest three bits reserved for the USB OTG controller's internal use. When a write is performed to the SPRAM through the L3 slave interface, bits 32 through 34 of the internal data bus are tied to 1, to enable the ECC bits to be initialized.

Note: Software cannot access the SPRAM beyond the 32-KB range. Out-of-range read transactions return indeterminate data. Out-of-range write transactions are ignored.

Host Operation

Host Initialization

After power up, the USB port is in its default mode. No VBUS is applied to the USB cable. The following process sets up the USB OTG controller as a USB host.

1. To enable power to the USB port, the software driver sets the Port Power (`prtppwr`) bit to 1 in the Host Port Control and Status Register (`hpprt`) of the Host Mode Registers (`hostgrp`) group. This action drives the V_{BUS} signal on the USB link.

The controller waits for a connection to be detected on the USB link.

2. When a USB device connects, an interrupt is generated. The Port Connect Detected (`prtConnDe t`) bit in `hpprt` is set to 1.
3. Upon detecting a port connection, the software driver initiates a port reset by setting the Port Reset (`prtrst`) bit to 1 in `hpprt`.
4. The software driver must wait a minimum of 10 ms so that speed enumeration can complete on the USB link.
5. After the 10 ms, the software driver sets `prtrst` back to 0 to release the port reset.
6. The USB OTG controller generates an interrupt. The Port Enable Disable Change (`prtENCHng`) and Port Speed (`prtspd`) bits, in `hpprt`, are set to reflect the enumerated speed of the device that attached.

At this point the port is enabled for communication. Keep alive or SOF packets are sent on the port. If a USB 2.0-capable device fails to initialize correctly, it is reported as a USB 1.1 device.

The Host Frame Interval Register (*hfir*) is updated with the corresponding PHY clock settings. The *hfir*, used for sending SOF packets, is in the Host Mode Registers (*host grp*) group.

7. The software driver must program the following registers in the Global Registers (*globgrp*) group, in the order listed:
 - a. Receive FIFO Size Register (*grxfsize*)—selects the size of the receive FIFO buffer
 - b. Non-periodic Transmit FIFO Size Register (*gnptxfsize*)—selects the size and the start address of the non-periodic transmit FIFO buffer for nonperiodic transactions
 - c. Host Periodic Transmit FIFO Size Register (*hptxfsize*)—selects the size and start address of the periodic transmit FIFO buffer for periodic transactions
8. System software initializes and enables at least one channel to communicate with the USB device.

Host Transaction

When configured as a host, the USB OTG controller pipes the USB transactions through one of two request queues (one for periodic transactions and one for nonperiodic transactions). Each entry in the request queue holds the SETUP, IN, or OUT channel number along with other information required to perform a transaction on the USB link. The sequence in which the requests are written to the queue determines the sequence of transactions on the USB link.

The host processes the requests in the following order at the beginning of each frame or microframe:

1. Periodic request queue, including isochronous and interrupt transactions
2. Nonperiodic request queue (bulk or control transfers)

The host schedules transactions for each enabled channel in round-robin fashion. When the host controller completes the transfer for a channel, the controller updates the DMA descriptor status in the system memory.

For OUT transactions, the host controller uses two transmit FIFO buffers to hold the packet payload to be transmitted. One transmit FIFO buffer is used for all nonperiodic OUT transactions and the other is used for all periodic OUT transactions.

For IN transactions, the USB host controller uses one receive FIFO buffer for all periodic and nonperiodic transactions. The controller holds the packet payload from the USB device in the receive FIFO buffer until the packet is transferred to the system memory. The receive FIFO buffer also holds the status of each packet received. The status entry holds the IN channel number along with other information, including received byte count and validity status.

For generic hub operations, the USB OTG controller uses SPLIT transfers to communicate with slower-speed devices downstream of the hub. For these transfers, the transaction accumulation or buffering is performed in the generic hub, and is scheduled accordingly. The USB OTG controller ensures that enough transmit and receive buffers are allocated when the downstream transactions are completed or when accumulated data is ready to be sent upstream.

Device Operation

Device Initialization

The following process sets up the USB OTG controller as a USB device:

1. After power up, the USB OTG controller must be set to the desired device speed by writing to the Device Speed (*devspd*) bits in the Device Configuration Register (*dcfg*) in the Device Mode Registers

(`devgrp`) group. After the device speed is set, the controller waits for a USB host to detect the USB port as a device port.

2. When an external host detects the USB port, the host performs a port reset, which generates an interrupt to the USB device software. The USB Reset (`usbrst`) bit in the Interrupt (`port reset`) register in the Global Registers (`globgrp`) group is set. The device software then sets up the data FIFO buffer to receive a SETUP packet from the external host. Endpoint 0 is not enabled yet.
3. After completion of the port reset, the operation speed required by the external host is known. Software reads the device speed status and sets up all the remaining required transaction fields to enable control endpoint 0.

After completion of this process, the device is receiving SOF packets, and is ready for the USB host to set up the device's control endpoint.

Device Transaction

When configured as a device, the USB OTG controller uses a single FIFO buffer to receive the data for all the OUT endpoints. The receive FIFO buffer holds the status of the received data packet, including the byte count, the data packet ID (PID), and the validity of the received data. The DMA controller reads the data out of the FIFO buffer as the data are received. If a FIFO buffer overflow condition occurs, the controller responds to the OUT packet with a NAK, and internally rewinds the pointers.

For IN endpoints, the controller uses dedicated transmit buffers for each endpoint. The application does not need to predict the order in which the USB host will access the nonperiodic endpoints. If a FIFO buffer underrun condition occurs during transmit, the controller inverts the cyclic redundancy code (CRC) to mark the packet as corrupt on the USB link.

The application handles one data packet at a time per endpoint in transaction-level operations. The software receives an interrupt on completion of every packet. Based on the handshake response received on the USB link, the application determines whether to retry the transaction or proceed with the next transaction, until all packets in the transfer are completed.

IN Transactions

For an IN transaction, the application performs the following steps:

1. Enables the endpoint
2. Triggers the DMA engine to write the associated data packet to the corresponding transmit FIFO buffer
3. Waits for the packet completion interrupt from the controller

When an IN token is received on an endpoint when the associated transmit FIFO buffer does not contain sufficient data, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to the USB host

If sufficient data is available, the controller transmits the data to the USB host.

OUT Transactions

For an OUT transaction, the application performs the following steps:

1. Enables the endpoint
2. Waits for the packet received interrupt from the USB OTG controller
3. Retrieves the packet from the receive FIFO buffer

When an OUT token or PING token is received on an endpoint where the receive FIFO buffer does not have sufficient space, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to USB host

If sufficient space is available, the controller stores the data in the receive FIFO buffer and returns an ACK handshake to the USB link.

Control Transfers

For control transfers, the application performs the following steps:

1. Waits for the packet received interrupt from the controller
2. Retrieves the packet from the receive buffer

Because the control transfer is governed by USB protocol, the controller always responds with an ACK handshake.

USB OTG Controller Address Map and Register Definitions

The address map and register definitions for the USB OTG Controller consists of the following region:

USB OTG Controller Module Registers Address Map on page 18-16

Registers in the USB OTG Controller Module. Only the Core Global, Power and Clock Gating, Data FIFO Access, and Host Port registers can be accessed in both Host and Device modes. When the USB OTG Controller is operating in one mode, either Device or Host, the application must not access registers from the other mode. If an illegal access occurs, a Mode Mismatch interrupt is generated and reflected in the Core Interrupt register (GINTSTS.ModeMis). When the core switches from one mode to another, the registers in the new mode must be reprogrammed as they would be after a power-on reset. The register address map is fixed and does not depend on the module configuration (for example, how many endpoints are implemented). Host and Device mode registers occupy different addresses.

Related Information

- **Introduction to the Hard Processor System** on page 1-1
The base addresses of all modules are listed in the *Introduction to the Hard Processor System* chapter.

USB Direct Access FIFO RAM Address Map

Name	Description	Start Address Offset	End Address Offset
Direct_FIFO	This address space is allocated for directly accessing the data FIFO for debugging purposes.	0x20000	0x3FFFF

Global Registers Register Descriptions

These registers are available in both Host and Device modes, and do not need to be reprogrammed when switching between these modes.

Offset: 0x0

gotgctl on page 18-40

The OTG Control and Status register controls the behavior and reflects the status of the OTG function.

gotgint on page 18-45

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

gahbcfg on page 18-47

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

gusbcfg on page 18-51

This register can be used to configure the core after power-on or a changing to Host mode or Device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

grstctl on page 18-57

The application uses this register to reset various hardware features inside the core

gintsts on page 18-61

This register interrupts the application for system-level events in the current mode (Device mode or Host mode). Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1 into the bit. The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically. The application must clear the GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

gintmsk on page 18-70

This register works with the Interrupt Register (GINTSTS) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the GINTSTS register bit corresponding to that interrupt is still set.

grxstsr on page 18-75

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the RxFIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

grxstsp on page 18-76

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the RxFIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

grxfsiz on page 18-77

The application can program the RAM size that must be allocated to the RxFIFO.

gnptxsiz on page 18-78

The application can program the RAM size and the memory start address for the Non-periodic TxFIFO. The fields of this register change, depending on host or device mode.

gnptxsts on page 18-79

In Device mode, this register is valid only in Shared FIFO operation. It contains the free space information for the Non-periodic TxFIFO and the Nonperiodic Transmit RequestQueue

gpvndctl on page 18-80

The application can use this register to access PHY registers. For a ULPI PHY, the core uses the ULPI interface for PHY register access. The application sets Vendor Control register for PHY register access and times the PHY register access. The application polls the VStatus Done bit in this register for the completion of the PHY register access.

ggpio on page 18-82

The application can use this register for general purpose input/output ports or for debugging.

guid on page 18-83

This is a read/write register containing the User ID. This register can be used in the following ways: -To store the version or revision of your system -To store hardware configurations that are outside the otg core As a scratch register

gsnpsid on page 18-84

This read-only register contains the release number of the core being used.

ghwcfg1 on page 18-84

This register contains the logical endpoint direction(s).

ghwcfg2 on page 18-85

This register contains configuration options.

ghwcfg3 on page 18-89

This register contains the configuration options.

ghwcfg4 on page 18-91

This register contains the configuration options.

gdfifocfg on page 18-96

Specifies whether Dedicated Transmit FIFOs should be enabled in device mode.

hptxsiz on page 18-96

This register holds the size and the memory start address of the Periodic TxFIFO

dieptxf1 on page 18-97

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf2 on page 18-98

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf3 on page 18-99

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf4 on page 18-99

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf5 on page 18-100

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf6 on page 18-101

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf7 on page 18-101

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf8 on page 18-102

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf9 on page 18-103

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf10 on page 18-104

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf11 on page 18-104

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf12 on page 18-105

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf13 on page 18-106

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf14 on page 18-106

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf15 on page 18-107

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

gotgctl

The OTG Control and Status register controls the behavior and reflects the status of the OTG function.

gusbcfg

This register can be used to configure the core after power-on or a changing to Host mode or Device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

This setting should not matter since UTMI is not enabled.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>PHY 8bit Mode</td> </tr> </tbody> </table>	Value	Description	0x0	PHY 8bit Mode	RO	0x0		
Value	Description									
0x0	PHY 8bit Mode									

Bit	Name	Description	Access	Reset
2:0	toutcal	Mode:Host and Device. The number of PHY clocks that the application programs in this field is added to the high-speed/full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the linestate condition can vary from one PHY to another. The USB standard timeout value for high-speed operation is 736 to 816 (inclusive) bit times. The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock are: High-speed operation: -One 30-MHz PHY clock = 16 bit times -One 60-MHz PHY clock = 8 bit times Full-speed operation: -One 30-MHz PHY clock = 0.4 bit times -One 60-MHz PHY clock = 0.2 bit times -One 48-MHz PHY clock = 0.25 bit times	RW	0x0

0x10	Flush all the transmit FIFOs in device or host mode.															

Bit	Name	Description	Access	Reset						
5	txfflsh	<p>Mode:Host and Device. This bit selectively flushes a single or all transmit FIFOs, but cannot do so If the core is in the midst of a transaction. The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. Verify using these registers: ReadNAK Effective Interrupt ensures the core is notreading from the FIFO WriteGRSTCTL.AHBIdle ensures the core is not writinganything to the FIFO. Flushing is normally recommended when FIFOs are reconfigured or when switching between Shared FIFO and Dedicated Transmit FIFO operation. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy_clk or hclk.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Flush</td> </tr> <tr> <td>0x1</td> <td>selectively flushes a single or all transmit FIFOs</td> </tr> </tbody> </table>	Value	Description	0x0	No Flush	0x1	selectively flushes a single or all transmit FIFOs	RO	0x0
Value	Description									
0x0	No Flush									
0x1	selectively flushes a single or all transmit FIFOs									
4	rxfflsh	<p>Mode:Host and Device. The application can flush the entire RxFIFO using this bit, but must first ensure that the core is not in the middle of a transaction. The application must only write to this bit after checking that the core is neither reading from the RxFIFO nor writing to the RxFIFO. The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>no flush the entire RxFIFO</td> </tr> <tr> <td>0x1</td> <td>flush the entire RxFIFO</td> </tr> </tbody> </table>	Value	Description	0x0	no flush the entire RxFIFO	0x1	flush the entire RxFIFO	RO	0x0

Bit	Name	Description	Access	Reset						
0	csftrst	<p>Mode:Host and Device. Resets the hclk and phy_ clock domains as follows:Clears the interrupts and all the CSR registers except the following register bits: - PCGCCTL.RstPdownModule - PCGCCTL.GateHclk - PCGCCTL.PwrClmp - PCGCCTL.StopPPhyLPwrClkSelclk - GUSBCFG.PhyLPwrClkSel - GUSBCFG.DDRSel - GUSBCFG.PHYSel - GUSBCFG.FSIntf - GUSBCFG.ULPI_UTMI_Sel - GUSBCFG.PHYIf - HCFG.FSLSPclkSel - DCFG.DevSpd - GGPIO - GPWRDN - GADPCTL All module state machines (except the AHB Slave Unit) are reset to the IDLE state, and all the transmit FIFOs and the receive FIFO are flushed. Any transactions on the AHB Master are terminated as soonas possible, after gracefully completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately. When Hibernation or ADP feature is enabled, the PMU module is not reset by the Core Soft Reset.The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit is cleared software must wait at least 3 PHY clocks before doing any access to the PHY domain (synchronization delay). Software must also must check that bit 31 of this register is 1 (AHB Master is IDLE) before starting any operation.Typically software reset is used during software development and also when you dynamically change the PHY selection bits in the USB configuration registers listed above. When you change the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No reset</td> </tr> <tr> <td>0x1</td> <td>Resets hclk and phy_clock domains</td> </tr> </tbody> </table>	Value	Description	0x0	No reset	0x1	Resets hclk and phy_clock domains	RO	0x0
Value	Description									
0x0	No reset									
0x1	Resets hclk and phy_clock domains									

gintsts

This register interrupts the application for system-level events in the current mode (Device mode or Host mode). Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1 into the bit. The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared

automatically. The application must clear the GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

gintmsk

This register works with the Interrupt Register (GINTSTS) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the GINTSTS register bit corresponding to that interrupt is still set.

grxstsr

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the RxFIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.
